developed fact that the endurance limit may be determined by noting the break in the rise-of-temperature curve in a series of stress reversals extending over only a few minutes. The upper diagram in Fig. 3 shows side by side the endurance curves (in this case plotted on simple logarithmic paper) and the corresponding heating curves, which show a break at the endurance limit. Fuller proof of the identity of the two points is given by the lower diagram, which represents a composite plot of all the tests so far made, each point being plotted with endurance limit as ordinate and heating limit as abscissa. None of the points departs materially from the straight line of equal values.

Strengthening Effect of Overstress—Some specimens which had stood 100,000,000 cycles without fracture, under stress just below the endurance limit, were re-tested under higher loads, and many of them ran up to 50,000,000 cycles or more although the stress in certain

cases was as much as 20 per cent above the endurance limit of the material in its original condition. This strengthening effect was especially noticeable in 0.37 carbon steel, normalized.

Relation of Endurance Limit to Ultimate Strength—From the two curves in Fig. 4 it may be seen that the endurance limit is very closely correlated to the ultimate strength of the steel, and only quite imperfectly to the elastic limit. This also agrees with the indications of the earlier tests. In this connection, however, the second report gives the following necessary caution: "The materials engineer should beware of regarding any single property of a metal—elastic limit, tensile strength, endurance limit, hardness, ductility, notched-bar value, etc.—as a complete indication of the usefulness of a steel. Static strength, resistance to impact, ductility under overstress, and resistance to repeated working loads are all important."

Effect of Overstress—In a number of tests the endurance specimen was first subjected to a few applications of direct tensile stress. As exhibited by the curves in Fig. 5, this preliminary stressing had no effect on the endurance test so long as it was well below the proportional limit, but above that limit it reduced the endurance 20 per cent.

Effect of Heat Treatment—When the temper of a hardened steel specimen is drawn, its endurance limit is not much affected until the drawing temperature exceeds 600 deg. Higher drawing temperatures pro-

duce a progressive decrease in endurance limit, as illustrated in Fig. 1. For nickel steel, both ultimate strength and endurance limit fall off slightly even with low temperatures of draw.

Combined Bending and Tension—An extended investigation of endurance under a range of stress other than complete reversal was begun during the past two years. The tests were made upon a rotating cantilever specimen loaded at its outer end, and stretched longitudinally by a heavy spiral spring bearing against a collar on the specimen. The endurance curves obtained proved to be exactly like those for reversed bending, but the endurance limit had a different value. The steels tested were a 0.53 carbon steel and a 3½ per cent nickel steel.

The results for the nickel steel, annealed, are reproduced in Fig. 6, where they are plotted in connection with a Goodman diagram. Professor Goodman, of Leeds, developed a hypothesis on the assumption that the varying component of stress has twice the effect of a steady stress, and that fracture cannot develop unless the sum of steady stress and twice the varying stress reaches the ultimate strength of the material. The shaded diagram in Fig. 6 represents the Goodman hypothesis. The plotted circles and the curved line passed through them represent the Illinois test results on this particular material. In all the tests it was found that the curve of maximum stress approached the horizontal in the neighborhood of the proportional

limit, while below the point of sharp bending the maximum-stress curve was not far from parallel to the minimum-stress line, in most instances.

A formula is proposed in the bulletin, to express the endurance limit (maximum stress) for any given ratio r of minimum to maximum, in terms of the endurance limit for completely reversed stress, S_{-1} :

$$S_r = \frac{1}{2}(r + 3)S_{-1}$$

The formula can be used only up to the limit at which the maximum unit stress reaches the proportional limit of the material; for most steels this eliminates ratios of minimum to maximum stress greater than zero. "Beyond the proportional elastic limit the static properties of the steel are the governing factors, rather than the fatigue properties."

Laying Large Cast-Iron Gas Main in Chicago

Work Expedited by Breaking Bell-Hole Material into Excavator Buckets and Calking with Air-Driven Tools

RAPID laying in Chicago last fall of $4\frac{1}{2}$ miles of one of the largest gas mains in the country involved $7\frac{1}{2}$ -ft. trenches which were excavated at one cut with bell-holes predetermined and the material broken down into the excavator. Other features of the work were rapid calking by pneumatic hammers, cumulative testing of the line, reduction of the speed of the pipe-lowering lines by a double set of blocks and placing the pipe on the original, undisturbed bottom of the trench. The line was laid by the Peoples Gas, Light and Coke Co., on Crawford Ave. from Thirty-ninth St. to Forty-fourth St., on Forty-fourth St. from Crawford Ave. to Hamlin Ave., and south on Hamlin Ave. from Forty-fourth St. to Seventy-first St., as a new connection to the distribution system on the south side of the river from the newly completed plant at Thirty-fifth St. and the Main Drainage Canal of the Sanitary District of Chicago. The new pipe serves three purposes: (1) It takes care of the maximum capacity of the new plant, (2) it acts as a storage holder and (3) it will supply the south and southwest sides of Chicago for many years.

With a 3-lb. drop in pressure on the 48-in. main between the pumping station at the holder at Thirty-fifth and Crawford Ave., and with the different lines feeding east out of the 48-in. main, the new main will pass a maximum of 3,000,000 cu.ft. per hour. The pressure maintained at the pumping station is from 6 to $6\frac{1}{2}$ lb. With a 1-lb. drop in pressure between the pumping station and Seventy-first St., a distance of nearly 5 miles, the 48-in. main will pass approximately 1,500,000 cu.ft. per hour.

The grade of the southwest side of Chicago drops gently to the north and all drainage flows to the Drainage Canal. It was decided that an easy grade should be given the 48-in. main to the north and that it should follow the natural contours of the ground. Two feet of cover was considered sufficient and by grading the line to the north, no drips would be necessary as the line would drain into the tunnel shaft at Thirty-ninth St.

All underground work was taken care of in advance, arrangements being made with the city water-works department to lower the mains deep enough to allow the 48-in. main to pass over them. A 30-in. main was

cut and lowered 8 ft. by the insertion of 45-deg. bends. Telephone conduits and high voltage wires were moved out of the path.

An accurate survey was made of Hamlin Ave. along the route of the main and a profile map was made showing obstructions. The proposed line was laid out on this profile map and the grade established. Test holes were dug at each street intersection so that an accurate knowledge of the obstructions would be available and on record.

Because the south end of the job was on the highest elevation, and the territory at the north end near the Drainage Canal was open country, having a gumbo soil, very soggy in the spring of the year, it was decided to start at the south end.

Nash Brothers, the contractor for all work but the

FIG. 1.—THREE COMPRESSORS FEED AIR UNDER 100-LB. PRESSURE INTO HEADER LAID ALONG TRENCH

As high as fourteen sets of calkers and twenty-six hammers worked from the header line. The compressors supplied a maximum of 210 cu.ft. of air per minute.

calking, sublet the excavation of the trench to W. C. Thorne, Oshkosh, Wis.

An excavator with auxiliary cutters and buckets for the wide trench averaged about 200 ft. per day, while the average of 186 ft. of pipe laid, the speed maintained up to Aug. 1, is believed to be a record for 48-in. gas or water main. After this time the progress was slower as the line paralleled the trench of another underground utility making it necessary to substitute a dragline for the excavator.

Including the expansion of the earth from the trench the excavation runs about 2 cu.yd. per lineal foot. The position of bell-holes was determined ahead of the excavation and men with bars and shovels cut out the recess, throwing the material into the buckets of the excavator, thus saving the labor of throwing the material out of the trench. Due to a 43-day period of dry weather in Chicago only single pipe-trench braces were required, the clay gumbo standing up well.

To lower the pipe slowly into the ditch and to assist in lining it straight, the single line on the hoist drum was reduced by means of a double set of blocks so that 1 ft. on the drum was reduced to a $2\frac{1}{2}$ -in. drop at the pipe. A 10-ton caterpillar crane followed closely behind the excavator. It took 6 min. to lift the 48-in. pipe from the bank, place it in the trench and drive it

FIG. 2—BREAKING BELL-HOLE MATERIAL INTO EXCAVATOR

Position of bell holes was predetermined. With the auxiliary cutters the excavator dug a trench 7 ft. wide.

home. Extreme care was taken in laying the pipe, each length of which weighs 4 tons. The trench was dug to grade, and the 4-in. blocking so laid that the top was on grade, making the whole pipe, with the exception of the bell, rest on the original, undisturbed bottom of the trench. Constant engineering supervision was needed to carry out this plan. Levels were taken on the ditch as the excavator worked, on the blocking before the pipe was laid and on the pipe line after laying for a permanent record.

The company maintains its own machinery and crew for calking. Immediately after the pipe was placed in the trench, the bell-holes were trimmed in preparation for the calkers. At no time during the progress of the work were the calkers more than twenty-five joints behind the last pipe laid. Joints were 5 in. deep and calked with 3 in. of wool yarn and 2 in. of lead wool. Calking was done by pneumatic hammers, two men to each joint. It required 8 lb. of wool yarn and 126 lb. of lead wool per joint. Two men averaged two joints per day.

Compressed air was furnished by three portable compressors capable of supplying a maximum of 210

cu.ft. per minute each at 100-lb. pressure. A header line laid along the trench was fed by two compressors. At times as high as twelve sets of calkers and twenty-six hammers worked from this header line. The header line was run about 600 ft. ahead of the point where the calkers worked, and, by aid of an extra compressor, two compressors were always connected to the line while one was being moved ahead. By this arrangement the calkers were never held up waiting for air while the compressors or the header line was being moved ahead.

As precautionary measures against ground or surface water it was decided to have on the job three pumps having a capacity of 50 gal. per minute each. A header line was laid along the top of the trench and 12-ft. lengths of hose were connected by unions to this header line and lowered into each bell-hole where there was water. The method proved satisfactory in keeping the bell-holes dry.

The progress of the work for a week was so arranged that the digging and laying of the pipe ended Saturday noon. All uncompleted joints were then finished Saturday afternoon, or on Sunday if necessary.

To test the line a 48-in. plug was put in the last pipe by means of the traction crane. When the last joint had been calked, the three compressors were hooked up to the line and it was possible to secure 15-lb. pressure in the line inside of 8 hours. The tests were cumulative, the air being placed on each week's work in addition to the line already finished.

The contractor backfilled the trench with a power backfiller and puddled the dirt by means of a fire-hose connection to hydrants at street intersections. Excess dirt, which amounted to $\frac{3}{4}$ cu.yd. per lineal foot of ditch, was loaded by a clamshell crane on traction wheels, into auto-dump trucks and hauled away from the job to be wasted on vacant property.

The line was completed early in October and on Oct. 15 gas under 1-lb. pressure was turned in to blow out the air. Three hours later analysis indicated all of the air had been displaced and the full 5-lb. pressure was then admitted.

The new main was laid under the direction of John H. Eustace, chief operating engineer, with W. G. Rudd, assistant operating engineer in charge of the engineering details. Supervision and construction were carried on by the department of streets, of which C. L. Day is general superintendent, John Ginley, assistant general superintendent, and F. S. Carnes, superintendent of the south division.

Automatic Train Control Needed

A rear end collision between two freight trains on the Illinois Central R.R. at Hammond, La., was caused by the failure of the engineer of the following train properly to observe and obey automatic block-signal indications. The director of the bureau of safety of the State Commerce Commission comments as follows: "This accident again directs attention to the necessity for an automatic train-control system which will operate and control a train whenever for any cause an engineer fails to see or heed danger signal indications. In accidents of this character involving automatic-block signals, such failure of the human element can not be fully checked and provided against except by the use of an automatic train-control system to supplement existing signal systems for the purpose of compelling obedience to such indications."

Hints That Cut Cost and Time

For the Contractor and the Engineer

Fire Hose Towers Protect Camps Despite Heavy Snowfalls

SEVERAL construction camps on the Big Creek project of the Southern California Edison Co. are located at elevations above 7,000 ft. where snow accumulates to great depths every winter. In the

CAMP FIRE PLUG DESIGNED
FOR WINTER SERVICE

highest camp, at elevation about 9,000 ft. a 20-ft. depth of snow is not unusual. With several hundred men in such camps and important work at stake, adequate fire protection in winter time has been given careful study with the result that instead of being put on the ground in the usual way, fire plugs, together with the necessary hose, have been located in wooden towers whose height varies with the average depth of the winter's snow.

These towers are located at strategic points throughout the camp and are arranged as shown in the accompanying illustration with the water main leading to the plug incased in earth or sawdust to prevent freezing and a small house on top of the platform in which lengths of hose can be stored.

Macadam Road Smoothed by Combining Dragging With Surface Treatment

BY A. H. HINKLE

Superintendent of Maintenance, Indiana Highway Commission

A NEW method of making smooth a rough macadam surface by the use of surface treatments combined with dragging, has been used with success on one of our state roads. The work in this particular instance consisted in combining the surface treating of an old macadam road with a process of dragging, which resulted in transforming a rough and irregular surface into one much smoother.

About two years ago a waterbound macadam road was built under traffic, a condition which prevents the surface from being smooth when completed. This surface had been treated with tar in 1922 but the irregularities were still prominent. This year it was decided to retreat the surface. The surface was first swept and about .18 gal. per square yard of tar was applied with a bituminous distributor; and a light coat of stone $\frac{1}{4}$ in. to $\frac{1}{2}$ in. in size spread thereon.

This part of the work was done by the ordinary method for any good surface treatment. The surface was then dragged with a road maintainer which scraped the screenings coated with tar into the depressions in the surface, leaving the road quite smooth. The surface was then given another treatment of tar of about the same amount as used in the first treatment, and another light application of clean screenings was applied. By this double treatment process and the dragging operations a smooth surface was left which ironed out under traffic. The grade of tar used was a medium heavy surface treatment tar with a viscosity of 25 to 40 at 40 deg. C. Dragging should be done not too soon after the first treatment is applied but before the tar has become set. Also, it is desirable to permit little traffic over the road after the dragging and before the second treatment of tar is applied.

While this method has not yet been attempted with asphalt, there is no reason why the same process would not be satisfactory if the right grade of asphalt is used.

Methods for Carrying Precise Levels Over Wide Bodies of Water

QUITE often surveying presents problems upon which there is little published data explaining the "best method" of solution. In river crossings, for instance, it will often be necessary to carry a line of precise levels over an arm of water too wide for ordinary sighting and not spanned by a structure of sufficient stability to carry a line of levels. In his recently-published Department of Commerce bulletin on "Use of Geodetic Control for City Surveys" Hugh C. Mitchell, mathematician of the U. S. Coast and Geodetic Survey, explains two precise methods of carrying levels across such wide bodies of water. Ten such crossings, varying in length from 790 to 4,400 ft., were met with in a survey of New York City.

The first of these is the fixed-target method and the second the movable-target method, and both will produce an accuracy comparable to what is attained in leveling over land. These methods are described by Mr. Mitchell as follows:

Movable-Target Method—On the New York City survey special targets were constructed for each river crossing. These targets had the same general design but differed in absolute dimensions and in some details of design, depending on the width of the crossing. They were clamped onto the regular level rods. The observations were made simultaneously from both sides of the river and required, therefore, two levels which were as nearly alike as possible. The instruments were very carefully adjusted and were set up on opposite sides of the river with the rods held on bench marks or turning points about 20 ft. distant from each. After each observer had read the near rod he then sighted across the river and by prearranged signal waved the target into position at the same time that the observer on the other side of the river was performing the corresponding operation.

In order to permit a change in atmospheric conditions to take place, five minutes were allowed to elapse before the targets were again waved into position for a new set. After

10 such sets had been obtained the observers changed stations, each observer taking his instrument with him, and 10 more sets were observed, followed by readings on the near rods. Such a series of observations will ordinarily give a satisfactory determination of the difference of elevation of the two rod stations. If the result should not have the accuracy desired, the atmospheric conditions should be carefully studied and more sets should be taken at such a time that the observations will be least likely to be subject to any abnormal refraction.

Particular attention should be paid to seeing that the line is not too close to the water, and that observations are not made when the sun is shining brightly in patches on the water through breaks in the clouds. There should be no change in the focus nor any disturbance of the line of collimation of the instruments in exchanging stations.

It is readily seen that the mean of simultaneous observations will be free from the effects of curvature and ordinarily from those of refraction. In practice it is best to combine the 10 readings on each rod in each set by taking a straight mean before subtracting to obtain an approximate difference of elevation. This also enables one to study the actual observations with the view of determining if any of them are beyond the limit of rejection.

A safe rule to follow in rejecting observations is given in "The Adjustment of Observations," by Wright and Hayford, who advise the rejection of each observation for which the residual exceeds five times the probable error of a single observation. Each observation for which the residual exceeds three and one-half times the probable error of a single observation should be examined, and if any of the conditions under which the observation was made were such as to produce any doubt it should be rejected.

The probable error of a single observation is computed from the formula

$$r = 0.6745 \sqrt{\frac{\sum v^2}{n-1}}$$

in which r is the probable error of a single observation, $\sum v$ is the sum of the squares of the residuals from the arithmetic mean, and n is the number of observations. Where an observation is rejected, it should, if possible, be replaced by another observation, in order that the computation may be kept as simple as possible by avoiding the introduction of unequal weights.

After correcting the approximate difference of elevation from the separate sets for index error of rod, rod length, and temperature, the results may be combined into one mean, giving the final difference of elevation of the rod stations. The computations may be made by combining either the means corresponding to simultaneous observations or the means representing a given instrument in its two positions. If the sets of observations are perfectly symmetrical, the final result will be independent of how the combination is made.

Fixed-Target Method.—In this method the micrometer screw of the instrument is used to make readings on the rod above and below the level line of the instrument. It is essentially a method of vertical angles into which the absolute values of the vertical angles do not enter. The stations are selected with due regard to water line and height above water surface, and the rods are held in place by guys. Two targets are clamped on each rod in such position that one is above and the other below the point on the rod intersected by the middle wire of the diaphragm when the instrument is level. A single observation consists of three readings of the micrometer, one when the middle wire bisects the upper target, another when the instrument is made level, and the third when middle wire bisects the lower target. The positions of the targets on the rod may be closely measured, using dividers and scale. The point at which the middle wire cuts the rod when the instrument is level may then be easily computed, the intercepts on the rod being in direct proportion to the differences of the micrometer readings.

The program of observing adopted by the U. S. Coast and Geodetic Survey in making a crossing over the Mississippi River at a point where the width was 1,200 m. (0.75 mile) was as follows.

Two instruments were used and the observations on the two sides of the river were made simultaneously. The near rod for each instrument was first read and then, on a signal from the observer in charge, observations were begun across the river and continued until the observer in charge had made 25 sets of observations, when, on signal, observing across the river ceased. The observers then changed stations, carrying their instruments with them, using care not to disturb the focus or line of collimation, and the program was repeated, except that the near rods were read last. The observers changed stations again and a third repetition of the program was made. This constituted a day's program and was repeated on at least one other day.

The reduction of observations made by this method do not differ materially from the computation where the movable-target method is used.

Table for Locating First Rivet of a Gusset Connection

A CONVENIENTLY arranged table for finding the distance from the center of a gusset-plate connection to the first rivet of a connected member is given by L. S. Owen, of Nashville, Tenn. The arrangement of the table may be understood from the sketch herewith,

TABLE FOR LOCATING CONNECTION RIVETS

in which for any given bevel of connected member the required rivet distance is found by reading from the table separately the items H and K , the first depending on the clearance width of the main member and the second depending on the edge distance of the rivet in the connected member. The table contains a double line of figures for each bevel, beginning with 1 in. in 12. The left-hand portion of the table, of which only a part is shown, gives the quantity H , the right-hand portion the quantity K . Values of H are given for various clearance widths from $\frac{1}{8}$ in. to 1 in. by eighths, and from 1 to 12 in. by inches. The right-hand part of the table gives the values K for various edge distances of the connected member from $1\frac{1}{2}$ to $2\frac{1}{2}$ in., multiples of these values being read from the table by mentally multiplying the value K . The required rivet distance is the sum of H , K , and the end distance of the rivet.

The double line of the table for each bevel represents separately case 1 and case 2 of the sketch, the upper line being for case 1, members of flat slope, and the lower line for case 2, members of steep slope. The complete table for all bevels from 1 in. to 12 in. may be calculated by the use of existing tables, and inserted in a handbook for use in detailing or checking drawings.

Narrow-Gage Tracks Used in Moving Houses to New Location

BY E. G. MCGILL

Contractor, Cumberland, Maryland

THE Sewerage Commission of Hagerstown, Md., desiring to get an outlet for the sewer and build a boulevard at the same time 100 ft. wide, has just completed moving eight six-room frame houses and one 12-room double brick and stucco house, a distance of one-third of a mile. The frame houses were moved on double lines of 3-ft.-gage track with 56-lb. rails.

The ground was in celery ridges, but by using a four-horse road grader a good level roadbed was obtained and narrow-gage ties were used in laying the tracks. Four pony trucks of four wheels each were coupled together from track to track by a 5x10 timber with a truss rod support. Then a 14x14 timber, 44 ft. long, resting directly over the king bolts, coupled up each set to suit the length of the building to be hauled with needles 12 in. x 12 in. x 36 ft. every 6 ft. crossing them as carrying timbers.

The houses all had full cellars, 6½ ft. deep, and by grading down and removing foundation walls the hauling frame was backed in under as far as possible. The fact that the buildings were all in a row and built up close together, high from the ground, made it easy to get in under them. Coming up crosswise to them it was necessary to turn each building one-quarter turn to set it on the platform. This turning was done on 4-in. rollers. In order to square each house with its new lot, and because a sharp curve had to be used in approaching new locations, tracks were laid on past the location and then thrown over the new site by crowbars.

FIG. 1—NARROW-GAGE TRACK USED IN MOVING HOUSES

When a house had to be turned around, a "Y" was employed.

The double brick house was not loaded on this railroad track but was rolled on six nests of alternating iron and wood rollers, ten to a nest.

A steel I-beam, 6x20 in. and 40 ft. long, was placed under each end wall of the building, and three pieces of 12x12 timber were placed up under the joist. Then 12x12's, 36 ft. long, and steel I-beams, 5½x15 in., 36 ft. long, were placed on 4-ft. centers as cross-needles.

The track was filled level with the surface of the rail with 4-in. crossing plank, with a third rail laid in the center, making a complete track of 3-ft. gage. Turning

From Job and Office

Hints that Cut Cost and Time

some very short curves, by cutting rollers to suit, the house was successfully moved. The time for truck moving was 10 ft. to the minute, and for the rollers 2½ ft. to the minute.

FIG. 2—250-TON BRICK HOUSE MOVED ON ROLLERS LAID ON NARROW-GAGE TRACK

The frame houses weighed about 100 tons each, and the brick house about 250 tons. These houses were moved to their new locations through a peat marsh, much water being encountered at places.

This work at Hagerstown, Md., was contracted for by the writer.

Los Angeles Hotel Moved to New Site

IN ORDER to make room for the new Los Angeles County Hall of Justice, the 6-story reinforced-concrete Alhambra Hotel has been moved 122 ft. and set on a new foundation. The method of moving is similar to that used in moving a Chicago warehouse, described in *Engineering News-Record*, April 26, p. 754.

The hotel was moved on 19 tracks, the structure being supported and tied together by steel girders running transversely and steel needles extending longitudinally. Each track consisted of four 60-lb. steel railroad rails laid on 6 x 6-in. wood ties resting on four 12 x 12-in. wood sleepers. Each girder was made up of three 15-in. steel I-beams bolted together; and there is one over each track resting on 2½-in. solid steel rollers which travel over the rails.

Two steel cables were used to pull the structure, one 2,500 ft. and the other 1,600 ft. in length. These cables are ½ in. in diameter, of plow steel, consisting of 6 strands of 19 wires each, and having a tensile strength of 32,000 lb. The cables run through two lines of sheaves, one set being fastened to 12 x 12-in. timbers set against the ends of the steel girders on the south side of the structure and the other set being fastened to iron stakes driven ahead of the tracks. There are 45 of these sheaves and the cables run back and forth from one line to the other like the lace in a shoe. Moving the structure was accomplished by teams operating the capstans.

Crane Excavates and Builds Cofferdam for Filtered Water Basin

EXCAVATION for the cofferdam for the filtration and coagulating basins at Benton Harbor, Mich., was carried out by the use of a crane and by sluicing, after the top layer of earth and clay had been stripped. The stripping of this top layer was started by hand, the material being hauled by teams to spoil banks; later teams and slip scrapers were used to hasten the work.

The material encountered below the top clay layer is a fine water-bearing sand which when dry is very compact but when wet is almost liquid. In places where the ground water was near the surface, it was removed by the use of a 6-in. steam-engine-driven centrifugal pump, indicated in the diagram as Pump 1.

The crane was then used for driving the wakefield sheeting, bracing and anchor piles and for excavating. A 2,800-lb. steam hammer was rigged on the 30-ft. boom of the crane and a 2½-in. jet line was used to help sink the sheeting through the sand. The details of the cofferdam are shown on the sketch. The sheeting was from 14 to 16 ft. high and was driven from 6 to 8 ft. below the foundation of the basin.

For excavating after the sheeting was driven, a ¾-yd. clamshell bucket was rigged on the crane, and excavation was made to an average depth of 5 ft.

The work of the crane is shown in the diagram, starting at position 1 in the northeast corner and driving the round piles along the east side, then moving to

CRANE HAS 28,000-LB. HAMMER AND 30-FT. BOOM

positions 2 and 3 and driving the round piles and sheeting along the north side and excavating to grade. The final location of the crane was position 4 for excavation and driving on the south side, the west side driving and the excavation in section A having already been finished.

Sluicing was done in the two sections designated on the diagram as B. By the use of pump 1 and an additional pump 2, the excavated material was sluiced over the site for the coagulating basin; the sand was stirred up and held in suspension by means of a 2½-in. jet line.

Location C could not be reached by either the pumps

DETAILS OF COFFERDAM OF FILTRATION AND COAGULATING BASINS AT BENTON HARBOR

Positions of the crane from which excavation and driving of the piles were done are numbered. Other methods of excavation are also indicated.

or the crane. So a slip scraper was rigged with a rope over the niggerhead of the crane and the material in C was pulled over to the south end of the cofferdam where the bucket could reach it.

When all the excavation had been made to approximate grade, drainage was accomplished by ditches along the sides of the cofferdam leading to a sump constructed in the northwest corner of the cofferdam. All mud holes were cleared and filled with clean material. Also, clean material excavated from the cofferdam was piled near by for use in backfilling.

When the concrete was poured, care was taken to keep the bottom of the cofferdam compact and solid, which was accomplished by the use of the pumps to keep the water level down. The finish grading was done by hand.

This work was carried out under the general supervision of Pearse, Greeley & Hansen, consulting engineers, Chicago.

Concrete Mixer with 50-ft. Boom

IN PAVING a new concrete highway near London, England, having a width of 50 ft. between curbs, the mixer moved outside of one curb line and the concrete was placed by a bucket traveling on a steel truss or boom which spanned the entire width of road. One end of the truss was carried by the traveling mixer outfit and the other end by a steel frame or tower. The bucket was of the tilting type, carried in trunnion bearings on hangers attached to a trolley running on the bottom chord of the truss and operated by a cable and drum.

Renewing Rails with Small Power Crane

A LIGHT self-propelling power crane which not only reduces the labor force required in renewing rails but increases the amount of work done has been designed and used extensively on the Atchison, Topeka & Santa Fe Ry. This machine, shown in the accompanying view, consists of a small flat car equipped with a timber mast and boom and a gasoline engine. A similar car may be attached as a trailer to carry a tool box. Only four men are required, even with heavy rails: one operates the hoist, another handles the rail tongs attached to the fall rope, and the others (one at each end) guide the rail into place.

This crew has laid as many as a hundred rails in an hour, according to W. F. Muff, roadmaster, Newton, Kan. And with the use of the machine a gang of a hundred men can be kept busy spiking, gaging and bolting up the new rails. On busy main track, 300

RAIL-LAYING CRANE: A. T. & S. F. RY.

rails have been laid in the morning, while the afternoon was then occupied in full spiking and bolting the track and disconnecting the old rails.

The machine was designed jointly by the late J. Raymond, formerly general superintendent of the A. T. & S. F. Ry., and J. F. McNally, now assistant superintendent at Emporia, Kan.

Fourth Scale for Log Log Slide Rule

BY C. S. JARVIS

Consulting Engineer, Salt Lake City, Utah

AMONG the special types of slide rule that have been developed from the original simple form, it is probable that the log log duplex slide rule has the widest range of application, as it combines the essential features of most of the other forms, and has the special advantage in the solution of exponential formulas. If the various formulas involved in the study of interest, annuities, and amortization are involved in such computations, it will be noted that a large percentage of the problems will require the use of factors from 1.0025 to 1.01, representing the amount of principal and monthly interest, where the rate per annum is from 3 per cent to 12 per cent.

Due to the rapid decrease in the values of the log log scale below 1.01 compared with the corresponding decrease in the series of numbers from which this scale is derived, the makers of slide rules have advised the use of suitable factors to render any number appearing between this limit and its reciprocal, 0.990, into a convenient form for use on the scales already provided. This necessitates the use of the same factor as a divisor, affected by the various exponents or root indices, thus

From Job and Office

Hints that Cut Cost and Time

requiring additional settings of the slide and increasing the labor involved and the chance for errors.

The writer had occasion to solve such problems, and found it worth while to provide an additional scale, which for convenience is called LL0, covering all values from the number 1.00105 to 1.01, or from the thousandth to the hundredth root of e , the base of Napierian logarithms.

The location of the graduations on the LL0 scale will be referred to the LL1 scale, and values given corresponding to various rates of interest per annum reduced to the monthly basis.

Interest per Annum, Per Cent	Interest per Month, Per Cent	Reading on LL0 Scale	Reading on LL1 Scale
1.26	0.105	1.00105	1.01
2	0.1666	1.0016667	1.01679
3	0.25	1.0025	1.0253
4	0.3333	1.003333	1.0338
5	0.41667	1.0041667	1.04245
6	0.5	1.005	1.05115
7	0.58333	1.0058333	1.0599
8	0.66667	1.0066667	1.0687
10	0.8333	1.008333	1.0865

While the above tabulation includes all of the most commonly used factors for computing interest compounded monthly, any intermediate value not provided for on either of the LL scales can be readily computed when account is taken of the relation existing between contiguous LL scales, the upper one being the tenth root of the lower. As an example, let it be required to locate the position on the LL0 scale of 1.0045833, principal and monthly interest corresponding to 5.5 per cent per annum.

Log 1.0045833 = 0.0019860.

Log 1.0468 = 0.019860 (the above logarithm multiplied by 10).

Therefore the position sought is immediately above 1.0468 of the LL1 scale.

Approximately this same value would be obtained by interpolation between adjacent graduations, but for best results it appears important that the entire LL0 scale should be added.

It will be observed that the above list of readings for the proposed LL0 scale shows a tendency of the numbers to the right of the decimal point to approach in value those immediately below on the LL1 scale, but the location is one space farther to the right. Thus the tenth root of 1.01 is 0.00105; of 1.03 is 1.003; and of 1.001 is 1.0001 to the nearest practicable reading, either from seven-place logarithmic tables or on portable slide rules. Therefore, if the LL0 scale is provided as above suggested, then the whole field will be effectually covered between 1.01 and 1.0001 for exponential formula computations involving factors within those limits.

As one of the most elementary illustrations of the use of the LL0 scale, let it be suggested to find the time required for an investment to double itself at interest compounded monthly, rate one-third of one cent per month, nearly comparable with 4 per cent per year.

Here the formula becomes $(1.003333)^n = 2$.

Taking logarithms of each side, $n \log 1.003333 = \log 2$.

From Job and Office

For Contractor and Engineer

Solving for n ; $n = \frac{\log 2}{\log (1.003333)}$
Log $n = \log \log 2 - \log \log 1.003333$.
Placing the left index of the slide under 1.003333 of LL0, read 208.3 on C scale under 2.00 of LL2; 208.3 months = 17.36 years.

Following is the solution by logarithmic tables:
log 2 = 0.3010300 log 1.003333 = 0.0014451
log log 2 = 9.4786098 log log 1.003333 = 7.1598979
Subtracting, 7.1598979
log 208.311 = 2.3187119

The specific reason assigned by instrument manufacturers for not continuing the graduations below 1.01 on the log log scales, the steep slope of the log log curve which passes through minus infinity at abscissa = 1, is a favorable factor in computations involving the LL0 scale, as it effectively magnifies the graduations and conduces to accuracy.

Accounting for Highway Equipment

IN STATE road maintenance, accountability for the wide variety and great number of tools and equipment used has always presented serious difficulties. Because roads upon which equipment is used are so widely scattered, keeping track of tools is not always an easy matter. In a recent issue of the official organ of the Kentucky State Highway Commission, R. F. Albert, assistant engineer of maintenance, explains how that state takes care of its road equipment. The article as abstracted is given in the following paragraphs:

For the purpose of administration and field supervision the state is divided into six districts; at the headquarters of each is the district office, where equipment records are kept. In turn, each district is subdivided with a superintendent of maintenance in charge of each sub-district.

That superintendent keeps all records pertaining to the various articles of equipment assigned for use on the roads in his sub-district and in storage at his headquarters. In order to account properly for the equipment both in use and storage three forms are used.

First, the patrolman's, foreman's or resident superintendent's form, shown herewith, carries at the end of each month a list of equipment actually in use on that project. This form is forwarded to the superintendent of maintenance, who checks up the report against the previous monthly report and data he has relating to the assignment or release of any equipment.

The second form is that compiled by the district superintendent from data contained in all reports from the patrolmen, foremen and resident superintendents. After such data are compiled, the equipment in storage in the sub-district is listed immediately following. Upon the receipt of this form at district headquarters, it is checked with the information contained in the previous monthly report on assignment or release of equipment. A copy of each sub-district report is retained in the district office, the originals being forwarded to the equipment engineer at the central office.

The third is compiled from the information contained in the superintendent's equipment report. This is filed in the district office and in the central office for each district. The form is designed to show the balance on hand of each article of equipment at the beginning of the month, the number of articles both assigned to and released from each district.

With the use of these forms it is possible to know at all times the number of articles of any kind of equipment in a district, its location according to project, and the amount and kind of equipment not in use. It saves time and expense in locating equipment, prevents loss through neglect and unnecessary expenditure for new material.

ARRANGEMENT OF STRUCTURES AT BIG CREEK CAMP
adit camps, some of which are located upon precipitous walls of the canyon where level space could be obtained only by excavating benches. The accompanying illustration shows the arrangement of compressor house, mess hall and bunk houses at Camp 35.

The adit enters the canyon wall in a narrow draw or ravine and by excavating at the adit entrance, sufficient space was provided for the main buildings. The bunkhouses, however, could not be located in this limited space and accordingly were distributed as shown in the illustration. Some were made readily accessible by building them on timber trestle work alongside the road built for construction purposes through the canyon. Others, set on the steep hillside above, were made accessible by means of ladders or cleated ramps.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Determining Water Power Storage

Sir—Dr. George E. Lyon's article in your August 9 issue, p. 235, on "Determining Regulated-Flow Duration Curves Graphically," describes an admirable method for working out water power problems involving storage. The most efficient storage capacity for a given site is readily determined by its means.

The writer, having made repeated use of this method, wishes to submit the following additional suggestions with a view to simplifying the numerical work and adding to the utility of the methods. Instead of billions of cubic feet, the day-second-foot will be found the more convenient unit for this work. A day-second-foot may be defined as the quantity of water corresponding to one cubic foot per second flowing for a period of one day of 24 hours. It is, therefore, at once a rate of flow as well as a unit of volume. Its value will be apparent from the following.

In Table I, page 235, instead of writing down the mean monthly flow in second-feet as shown in the third column, head this column "monthly discharge in day-second-feet," and enter in it the total day-second-feet for each month, obtained by adding the daily discharges in second-feet for each month. These figures are nearly always available, being a step in the computation of the mean monthly flow figures used by Dr. Lyon. In fact, tabulated data of stream-flow such as are supplied on request by the U. S. Geological Survey always contain these monthly totals, except when the data are clipped from some publication. (In the latter case it would, of course, be necessary to multiply the mean monthly flow by the number of days in the month in order to obtain the total day-second-feet.) Next, obtain the last column of Table I by merely adding progressively the day-second-foot figures appearing in the preceding column, using an adding machine equipped to give sub-totals. This will save much time and effort over Dr. Lyon's method. Head this last column "accumulated discharge in day-second-feet."

The diagrams are then platted as before, except that the ordinates in Fig. 2, page 236, will be day-second-feet instead of billions of cubic feet, and the abscissas will be days instead of inches. Besides simplifying the numerical work, the principal advantage resulting from the use of the day-second-foot will be found to lie in its dual capacity above referred to. Thus, in the diagram (Fig. 2) it functions either as a rate of flow, or as a quantity of storage, depending upon which is desired. In the latter capacity it affords a quick conversion into acre-feet, as one day-second-foot is equivalent to 1.983 acre-feet, or for all practical purposes 2 acre-feet. Therefore, the ordinates of a diagram like Fig. 2, when platted in day-second-feet can also be made to read acre-feet by multiplying the day-second-feet by two, the error so involved being less than 1 per cent, which is negligible in most studies of this kind.

The writer has been in the habit of plating against Fig. 2 a curve showing the state of depletion of the reservoir from day to day, and it will be seen from what has been said above that the acre-foot ordinates are most convenient for this purpose. Where evaporation is large and has to be taken into account, an evaporation curve can be platted likewise across the diagram, its ordinates being derived by computation from the state of reservoir depletion curve, and the evaporation in acre-feet applied as a correction to the latter.

In conclusion, the writer would suggest the use of the term "summation hydrograph" in lieu of "mass curve."

The latter name was derived from earthwork computations in balancing railroad cuts and fills. It is a misnomer when applied to hydraulic computations. About 14 years ago the writer started the use of the term "summation hydrograph" as being the most appropriate name for a mass diagram such as is referred to in Dr. Lyon's article, and he has been gratified to note its adoption by many leading men in the profession.

Chattanooga, Tenn.,
Aug. 11, 1923.

GERARD H. MATTHES,
Consulting Engineer.

A Passion for Straight Lines

Sir—The editorial, "A Passion for Straight Lines," in the Aug. 2nd issue of *Engineering News-Record*, brings to mind the following exposition in Balzac's "Seraphita":

"Your geometry establishes the fact that the straight line is the shortest distance between two points, but your astronomy shows you that God proceeds only in curves. Who can judge then between rectilinear and curvilinear geometry? Between the theory of the straight line and the theory of the curve? The bullet which a man would shoot straight really goes in a curve. None of your savants has drawn the simple deduction that the curve is the law of the material world, but the straight line is the law of the spiritual world. Does not the love of great souls for the straight line show in them an intuition of heaven?"

This last sentence may console some engineers who, like Mr. Friedman, have been accused of sacrificing beauty to an engineering passion for straight line. They may further fortify themselves by reading the introduction to Miss Wormley's English version of "Seraphita" where the occult doctrines of the circle as the perfect figure and the effect of the curve on the development of architecture are gone into at some length, and where it is explained that Balzac has departed from his Swedenborg in this instance and has considered the circle as symbolic of the created or the Material, which perhaps appears more beautiful to us on an earthly plane than the straight line, though this represents the uncreated or the Infinite.

RUTH CANAVAN,
Librarian with Metcalf & Eddy.

A Curious Judicial Decision

Sir—I have read the review of the decision of the Pennsylvania Court of Quarter Sessions, declaring the Pennsylvania engineers licensing law unconstitutional, in your issue of Aug. 2, 1923. I could not but feel a considerable amount of self-contained amusement after studying the report of the decision. It brought me back to the days of my childhood, when we had to parse sentences. What struck me in reading over the resumé was the objection to the law on the ground that it was unconstitutional for the reason that it contained "more than one subject." As I said before, this brings me back to the days of my study of sentence formation and construction.

Is the subject of the bill in all fairness, and sensible interpretation, "an act to regulate the practice of professions," or is it an act to regulate the practice of engineering and land surveying? According to the judge's interpretation, if Pennsylvania is going to regulate the practice of the professions of lawyers, mechanical engineers, surveyors, civil engineers, "advertising engineers," electrical engineers, plumbing engineers, sanitary engineers, *ad infinitum*, I suppose that a special act would have to be passed for each of the particular kinds of engineers or occupations.

After all, does the foregoing not strike you as somewhat absurd especially when the regulation for all of the different kinds of persons in the several occupations might be a single regulation applicable to each. I predict that if there is any appeal from the decision there is a high probability of reversal on the ground I mentioned.

Cleveland, Ohio,
Aug. 14, 1923.

J. F. ROSS,
Attorney at Law.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

A Public Hearing on the Advisability of building a bridge across the Hudson River at New York City, will be held at the Army Building in New York on Monday, Aug. 27. The North River Bridge Co., of which Gustav Lindenthal is the head, has asked the War Department to approve the plans submitted by that company.

Abandonment of 122 Miles of the Hartford and Connecticut Western R.R., a subsidiary of the Central New England R.R., has been proposed by C. M. Sheafe, president of the H. & C. W. The reason given for the proposal is that the greater portion of the railroad is unnecessary and unprofitable. No action can be taken until the Interstate Commerce Commission has approved of the abandonment.

Premier Massey Has Formally Opened the new Otrira tunnel at Arthur's Pass, on South Island, New Zealand. The tunnel links the east and west coast of the island and replaces the dangerous coach route which formerly connected the two electrical coastal railways of that island. The tunnel is 5½ miles long and has a maximum gradient of 3 per cent. It is ½ mile longer than the Connaught tunnel in the Canadian Rockies, the longest tunnel on the American Continent.

Proposing to Build a Bridge Across the Niagara River at Fort Erie for vehicular and electric railway traffic, the Buffalo-Ft. Erie Public Bridge Co., Ltd., has received both Canadian and American charters and has now applied to the U. S. War Department and to the Dominion Department of Public Works for authority to bridge the Niagara River at that point. The proposed bridge will supersede the present ferry service and will cost between \$3,000,000 and \$4,000,000. The officers of the new bridge company are as follows: W. M. German, M. P. of Welland, president; Dr. William Douglas, Fort Erie, and Donald McGillivray, Port Colborne, vice-presidents; F. W. Wilson, Fort Erie, secretary-treasurer.

To Demonstrate the Ability of the army engineers and to reproduce various kinds of maps quickly during field operations, the Army Engineer Corps is sending its mobile map-making train to important points in the country. The train consists of a completely equipped laboratory mounted on army trucks, with facilities for making maps or reproducing them by photography, printing and lithographic processes. The train is manned by men of the 26th Engineers, the same unit that did such efficient map work in France. The train has just returned from Rio de Janeiro, where it was part of the American exhibit at the Brazilian Centennial Exhibition.

Denies Reported Electrification of Boston & Albany

The report that the New York Central plans to electrify the Boston and Albany and its new yards near Albany in the immediate future is not confirmed by G. W. Kittredge, the chief engineer. Mr. Kittredge says that the engineering department prepared a report on such electrification more than a year ago as a routine matter and that as far as he knows nothing more has been done about it.

Court Upsets Hoboken Garbage Contract Award

As a result of a suit brought by a lower bidder the New Jersey Supreme Court has set aside the award by the City Commission of Hoboken on July 31 of a five-year contract for the collection and disposal of garbage and ashes. The award was made to James J. McFeeley, a brother of Bernard McFeeley, the latter being a member of the City Commission and director of the Department of Public Safety. The accepted bid was for \$486,260. The lower bid of \$476,580, by Peter A. Peluso, the present contractor for the work, was passed over on the ground that Mr. Peluso gave unsatisfactory service last winter.

U. S. Navy Starts Scrapping Ships

With the receipt last week in Washington of France's formal acceptance of the naval disarmament treaty, all of the other signatory powers having previously signed, plans were immediately put into effect by the United States Navy to scrap ships condemned under the terms of the five-power treaty. Of the condemned ships eleven are under construction, seven of which are battle-ships located as follows: the "Indiana" and the "South Dakota" in New York; the "Montana" at Mare Island; the "North Carolina" at Norfolk; the "Michigan" at Quincy; the "Iowa" at Newport News; and the "Washington" at Camden. The battle cruisers, "Lexington" and "Saratoga" are being converted into airplane carriers. The other four battle cruisers, two of which, the "Constitution" and the "United States," are under construction at the Philadelphia Navy Yard, and two, the "Constellation" and the "Ranger," are under construction at Newport News, will be scrapped at once.

In addition to these vessels under construction, the following already completed will be scrapped "Virginia," "New Jersey," "Rhode Island," "Georgia," "Nebraska," "Connecticut," "Louisiana," "Kansas," "Vermont," "Minnesota," "South Carolina," "Michigan," and "New Hampshire."

The Navy Department has adopted three methods in disposing of the ships which methods cover in brief the three situations with which it is confronted: disposal of ships being constructed privately, those being built by the U. S., and those completed.

Grunsky Is Nominated as Am. Soc. C. E. President

Second Ballot Gives Him 162 More Votes Than Francis Lee Stuart—Other Official Nominees

C. E. Grunsky, with 1,671 votes as against 1,509 for Francis Lee Stuart, has been selected as the official nominee for president of the American Society of Civil Engineers. A total vote of 3,203 was canvassed, the tellers reporting results of the second ballot to the secretary of the society, August 15, in accordance with constitutional provisions. An aggregate of 3,395 votes was registered but 189 voted who were ineligible, one affiliate, and three signatures were illegible. The other official nominees are:

For vice-president, Zone 1, Lincoln Bush; vice-president, Zone 4, Oscar S. Bowen; directors, District 1, Thaddeus Merriman and Paul G. Brown (two to be elected in this district); director, District 4, Robert Farnham; director, District 11, Arthur O. Ridgway; director District 14, Alexander Maitland, Jr.; and director, District 15, J. M. Howe.

The complete vote follows:

For President:	
Carl E. Grunsky.....	1,671
Francis Lee Stuart.....	1,509
Void.....	11
Blank.....	12
Total.....	3,203
For Vice-President, Zone 1:	
Lincoln Bush.....	845
Void.....	6
Blank.....	37
Total.....	888
For Vice-President, Zone 4:	
George G. Anderson.....	399
Oscar S. Bowen.....	520
Void.....	3
Blank.....	9
Total.....	931
For Directors, District 1: (2 to be selected)	
Paul G. Brown.....	455
Thaddeus Merriman.....	513
Void.....	4
Blank.....	34
Total votes cast.....	1,006
For Director, District 4:	
G. H. Blakeley.....	20
Robert Farnham.....	98
John Meigs.....	89
Void.....	1
Blank.....	2
Total.....	210
For Director, District 11:	
Arthur O. Ridgway.....	231
Blank.....	18
Total.....	249
For Director, District 14:	
E. A. Hadley.....	43
Alexander Maitland, Jr.....	124
G. F. Maitland.....	11
Void.....	1
Blank.....	2
Total.....	181
For Director, District 15:	
J. M. Howe.....	140
J. H. Brillhart.....	60
Void.....	2
Total.....	202

W. F. Reeves is chairman of the Nominating Committee. The elections are to be announced at the annual meeting next January.

Secretary Work Explains Davis Removal

Answering Am. Soc. C. E., He Says Time Has Now Come for Business Administration

Secretary of the Interior Work has addressed the following letter to Secretary John H. Dunlap, of the American Society of Civil Engineers, in response to the request of that society for information regarding the recent removal of Arthur P. Davis from the position of director of the U. S. Reclamation Service:

"Your courteous inquiry of June 27, reply to which has been delayed because of my absence from the States, requires more than a categorical answer.

"The reclamation law, providing for the construction and operation of irrigation projects, mentions no official, but places the entire burden and responsibility of administering the law and of carrying out its purposes upon the Secretary of the Interior.

RESPONSIBILITY ON SECRETARY

"It creates no position known as Director or Commissioner of the Reclamation Service, nor any other position, but places the whole responsibility for selection of agencies for the performance of his work on the Secretary of the Interior.

"In the beginning, necessarily, the work was the construction of projects involving engineering skill, but with their completion there grew up another aspect, namely, the problem of the water-users and the collection of the original cost as contemplated by the law. It is thought that these problems, which involve dealing with the farmers individually, could be best handled by a practical business man familiar with the conditions peculiar to irrigation in the West.

"The return of the enormous investment made by the Government will necessitate help and advice to the farmers on the projects, along the line of subdivision of large land holdings, getting more settlers on the projects, securing creameries, sugar factories and other industrial enterprises; more intensive farming, diversification of crops and co-operation with the owners and tenants on 53,000 farms as to packing, handling and marketing their products by men who have been trained along these lines.

"This does not mean a diminished construction program, but rather an increased and accelerated construction, because with the money returned to the Government under efficient business management there will be freed a fund to continue construction that would otherwise be retarded.

"To handle the engineering work the engineering force of the service remains efficient, with the same chief engineer at its head who has been engaged in the construction work for many years. There is no thought of minimizing the importance of reclamation engineering. It was my purpose to retain Director A. P. Davis in the Reclamation Service as a consulting engineer, he at first consenting but subsequently declining the appointment.

"The Secretary of the Interior, who alone is charged with the execution of the Reclamation Act, desires the greatest possible efficiency—not alone efficiency in one phase of the work, but

Moffat Tunnel Bids to Be Received Sept. 12

Bids for the construction of the Moffat tunnel through the Colorado Rockies, will be received Sept. 12, and not Sept. 16, as previously announced. Bids were originally to have been opened Aug. 25.

Grounds and Building Committee for Philadelphia Fair

The Grounds and Building Committee for the Sesquicentennial Fair in Philadelphia in 1926 has been announced by Ernest T. Trigg, chairman of the Fair Executive Committee. On the committee, which already numbers fifty-eight, are many engineers, architects and other notable Philadelphians. The chairman of the committee is Howard B. French, a former president of the Philadelphia Chamber of Commerce, and the vice-chairman is William F. James, ex-president, Engineers' Club of Philadelphia. On the executive committee, besides the two just named, are E. B. Temple, assistant chief engineer, Pennsylvania R.R., and George S. Webster, of the Delaware River Bridge Joint Commission.

White River Power Project

A hydro-electric development to produce 160,000 primary electrical horsepower on the White River in the heart of the Ozark Mountains is proposed by the North American Co. The proposed development includes the construction of a dam 225 ft. high and 1,800 ft. long at the crest, which will form a lake nearly 100 miles long to cover an area of 150,000 acres. The Dixie Power Co., which is authorized by the State of Arkansas to construct water power projects on the White River, has received a preliminary permit from the Federal Water Power Commission, and has given Hugh L. Cooper & Co. an option on all its rights and holdings.

efficiency in every phase and aspect of reclamation. He believes that is made change to which you refer is made necessary by existing conditions; for unless improvement can be brought about many projects will be abandoned entirely by settlers—some have already gone—and the Government not only will lose millions of dollars invested, but the settlers themselves will lose time, labor and money already placed by them on their farms.

"Although it is primarily essential to construct dams and ditches, these are not alone enough to secure successful farming to settlers, for whom reclamation was instituted.

"All of our reclamation projects are not prosperous. It is not a question now of engineering so much as it is one of business acumen and operation. The men on the project must reimburse the Government for its millions of dollars advanced for the reclamation of land through irrigation, and our reorganization with this in mind seemed necessary.

"Because of the publicity I am advised this matter has obtained, I am taking the liberty of giving my letter to you to the press, that it may answer other similar inquiries."

Interior Department Tells New Reclamation Policy

Press Memorandum of Aug. 17 Calls for Greatest Efficiency From Officials Concerned

On Aug. 17 the Department of the Interior issued the following "Memorandum to the Press." This memorandum, and the foregoing letter from Dr. Work to the American Society of Civil Engineers, are commented on in the editorial pages of this issue:

"Inculcation of business principles into the operation of existing reclamation projects and in the construction of new projects is contained in a tentative policy adopted by the Reclamation Bureau of the Department of the Interior for the future.

"Made public today by Secretary of the Interior Work this tentative policy calls upon all project managers and engineers of the Bureau to bring about the greatest possible efficiency both in assisting the farmers in selecting, raising, and marketing of their crops and in reducing the cost of building new irrigation works. An outline of proposed policy follows:

"Existing Projects—Reduce overhead costs; deal with projects and water users as an engineering and business problem; encourage subdivision of large holdings into small farms, when better farming will follow; encourage and assist farmers to diversify and rotate their crops; aid in securing creameries, sugar factories, and other industries within or near the project limits to the end that a ready and profitable market for the products of the farm may at all times exist and be available; co-operate with the farmers in the packing, handling, shipping, and marketing of their products to the end always, that the maximum of return with the minimum of expense may come to the farmers; and impress on water users the idea that the Government money advanced for the construction of these projects was temporarily for their benefit in the nature of a loan without interest.

"New Projects—The West demands and should have additional reclamation projects where and when feasible; recommend against any new project where the cost is so high that there is no reasonable probability of farmers being able to repay construction costs (such action will advance and not retard meritorious reclamation projects); recommend against any new projects where the probable cost of operation and maintenance, through pumping or otherwise, will be too heavy a burden for the water users to carry annually; make not only engineering studies of proposed projects, but studies of soil, climate, and markets, including kinds of fruit, grains, or other crops which the soil and climate will permit to be grown profitably; make careful study of probable annual cost of operating and maintaining a project when built, including cost of drainage systems, if the project is undertaken see to it that cost of construction is accurately calculated, so that when the work is completed an unexpected and unestimated burden does not rest upon the water users because of underestimated construction cost; in brief, establish a real, actual and helpful working co-operation with the farmer."

Federal Building Contract Form Contains Arbitration Provision

The standard form of building and construction contract to be used by all departments of the Federal Government contains provision for arbitration of disputes over time or finances, as tentatively agreed upon by the Interdepartmental Board of Contracts and Adjustments. Heretofore the general practice in Government contracts has been that there should be no appeal within the Government from the decision of the contracting officer.

The Associated General Contractors hails the adoption of this arbitration clause as "an epochal concession."

The adjustment clause as tentatively adopted is given in the following paragraphs:

"Except as otherwise specifically provided in this contract, all claims, doubts, and disputes shall be decided by the contracting officer and the contractor shall promptly proceed with the work under such decision.

"The decision of the contracting officer shall be final and conclusive except as to the element of time and the financial consideration involved, and, unless within twenty days after which decision the contractor applies, in writing to the head of the department or independent establishment concerned for a review of the decision as to the elements of time and financial consideration involved, the decision of the contracting officer shall also be final and conclusive as to the questions involved in these elements.

"The head of the department or independent establishment shall promptly render his decision in writing. He may, however, before rendering his decision, refer questions raised upon review to either the board of contracts and adjustments of the department or independent establishment for which the work is being done or to the Interdepartmental Board of Contracts and Adjustments for report and recommendation thereon. His decision, when rendered, shall be final and conclusive and carried out by the parties as within the contemplation of this contract, unless within thirty days after such decision the contractor shall bring suit or give written notice to the head of the department or independent establishment of his intention to bring suit in court to determine his legal rights involved in such decision."

Members of Bureau of Housing and Regional Planning Named

Five lay members have been named to serve with three officials of New York State as a Bureau of Housing and Regional Planning in the State Department of Agriculture. The chairman of the bureau is Clarence S. Stein, an architect of New York City, who was secretary of the recent New York State Reconstruction Commission. Mr. Stein is also secretary of the Regional Planning Association of America. Another of the five lay members of the new bureau is Walter Stabler, controller of the Metropolitan Life Insurance Co., New York City. The ex-officio members include the state architect, state industrial commissioner, and Frederick Stuart Greene, state highway commissioner. An advisory commission is proposed.

Results of Engineer-Promotion Tests at Philadelphia

Announcements just made public show that there was only one candidate for the office of chief and three for that of deputy chief of the Bureau of Highways of Philadelphia, as a result of the non-assembled competitive promotion examinations.

John H. Neeson was the single candidate for chief. He has headed the Division of Street Cleaning since the city took over the work of street cleaning, garbage and ashes collection, etc., in 1921, and has been acting chief of the Bureau of Surveys since F. C. Dunlap was transferred from that position to chief of the Bureau of Water some weeks ago. It is expected that Mr. Neeson will receive the permanent appointment soon.

Percy F. Proctor led the three candidates for the position of deputy chief. He has been appointed to that position.

The two positions pay salaries of \$8,000 and \$6,000 a year. The examination for chief was open to all engineers in the service of the city of Philadelphia, receiving \$4,000 or more per annum, while for deputy chief examinations were open to any engineer in the city service receiving \$2,500 or more, the latter exclusive of the bonus. Candidates for chief were required to have an education equivalent to graduation in engineering from a university of recognized standing, besides fifteen years of general engineering experience, six years of which must have been in responsible charge and direction. For deputy chief, corresponding requisites held good except that ten years of general engineering experience and five years of highway construction and maintenance or street cleaning work were acceptable. Candidates were not required to appear at any place for written examination, but submitted a statement of their training and experience and wrote a paper on practical problems. They appeared before the Civil Service Commission for an oral interview on personal fitness. Training and experience was given a weight of 4.5; discussion of practical problems, 3; the oral interview for personal fitness, 2.5.

13 Countries Represented at Standardization Conference

An unofficial conference of the secretaries of various standardizing organizations was held early in July at Zurich, Switzerland. This was the second conference of its kind held, the first conference having taken place in London in April, 1921. At that conference the secretaries of seven standardizing organizations were present, whereas the Zurich conference was attended by secretaries of thirteen different countries—Austria, Belgium, Canada, Czechoslovakia, France, Germany, Great Britain, Holland, Italy, Norway, Sweden, Switzerland and the United States.

The conference, which lasted from July 3 to July 6, was given over to a discussion of the practical application of standards in the various countries and of the extent to which international collaboration is possible. Dr. Paul G. Agnew, of the American Engineering Standards Committee, attended.

More Details of Nyack Accident Are Received

Further details of the accident which happened Aug. 9 near Nyack, N. Y., and which resulted in the death from scald and shock of six women (see *Engineering News-Record*, Aug. 16, p. 282), when a pleasure bus rammed a concrete mixer, have been received from James H. Sturdevant, division engineer of the state highway commission. Mr. Sturdevant reports as follows:

"Along the side of the freshly laid concrete, over a roadbed that had been fine graded, the first bus passed without any difficulty. The second bus struck the nut on the end of the bolt which holds the upper hand hole plate in place and pulled it to one side, allowing the live steam to pour into the bus and scald its occupants. . . . There are seven uprights to hold the roof over the seats of the bus, and it was the second upright from the rear which struck the nut on the mixer."

An investigation is now being made, but as yet no report has been made to any of the state highway officials.

Power Plant Proposed for Cherokee Bluffs, Ala.

WORK will start in the near future on the Alabama Power Co.'s new hydro-electric plant at Cherokee Bluffs on the Tallapoosa River near Dadeville, Ala. This new plant will have an ultimate capacity of 132,000 hp., but the first installation will be two units of 44,000 hp. each. The Cherokee Bluffs dam will have a height of 120 ft. from the base to the top of the crest gate. It will be 800 ft. long and contain nearly 200,000 yd. of concrete. The reservoir formed by this dam will have an area of 25,000 acres, and will contain over 25,000,000,000 cu. ft. of

water. This large storage capacity will make it possible to use this reservoir to regulate the flow of the Tallapoosa and Alabama Rivers. As there is no town near the site that can be used for the accommodation of workmen and their families, the Alabama Power Co. will build a town at the site which will be able to accommodate 3,000 people. It will be equipped with water supply and sewage-disposal plant, hospital, recreation hall, a commissary and mess hall, and provided with electric light and power. The total cost of the work is estimated at \$10,000,000.

Random Lines

The Way Out in Germany

Sir—Further regarding "belting," "kitchen," and "exterminating" engineers! It seems that we are now going through what some of the European countries—notably Germany—experienced some fifteen or more years ago. At that time there was such a craze for the term "engineer" that every safety-pin manufacturer so dubbed himself. The term fell into considerable disrepute, or at least may be said to have lost its standing, and it was followed by the new term "Diplom Ingenieur," abbreviated "Dipl. Ing." This very rapidly solved the entire problem, for it was illegal for anyone to use the title "Diplom Ingenieur" unless he actually had a diploma from one of the recognized engineering schools. The use of the title without the prefix "Diplom" was thus an admission that the holder of it was in fact no real engineer.

It must be borne in mind however that, in Germany at least, the object was more a desire to maintain the class distinction than the purely professional purpose which it is to be hoped is the end in view in this country. W. D. B.

After reading a few accounts of the coal controversy the average citizen begins to wonder how any such dispute is ever settled. Apparently the acceptance of one side's proposal by the other side is *prima facie* evidence to the first side that it has gone too far, so it withdraws the proposal.

* * *

Not Entirely Hopeless

Those in charge of one of our monthly magazines of review must be profoundly depressed if the contents of their August issue is any guide. Hidden among a few hopeful stories we find the following titles: "Wets Destroying Nation," "Decadent Fiction," "Focusing the Light on Our Indian Scandal," "Scrambled Households Menace Whole Fabric of Society," "Civilization Deteriorating—The Decay of Public Spirit, Disregard of the Law," etc., etc., etc. We do not belong to the Pollyanna school or hold entirely with the *American Magazine* inspirational type of current literature, but we find it hard to believe that we are going completely to the dogs here in this country. Any nation which can rise one morning to find that while it slept its ruler has died and another one already taken his place and which can then proceed with its normal business with no feeling of insecurity to add to its great sense of personal loss has gone far toward the stabilization of its whole mechanism which no amount of comparatively minor disturbances can destroy.

Montreal Increases the Capacity of Its Grain Elevators

Work on the first unit of the new grain elevators at Tarte Point, Montreal, is being carried on day and night. It will have a capacity of 2,000,000 bu. and the completed layout will have a capacity of 10,000,000 bu. The plan also calls for four traveling marine towers, for unloading from lake ships, and for unloading points for railway cars. It also provides for five berths for loading ocean ships, each berth having facilities for loading 30,000 bu. an hour, while the unloading facilities from lake ships will be able to handle 60,000 bu. an hour and from railroad cars of 48,000 bu. an hour. Work is also in progress on elevator B at Windmill Point to increase the capacity of that plant to 1,125,000 bu. This work is being done by the Montreal Harbor Commission.

Want Clearer Decision on Rate-Making Values

Washington Correspondence

Declaring that the decision rendered in the Atlanta Gas rate case was at such variance with the decisions in the Bluefield Water Works case and the Southwestern Bell Telephone case as to cast doubt as to the law, the Georgia Railway and Power Co. and its lessor, the Atlanta Gas Light Co., filed a petition in the U. S. Supreme Court on August 11 in support of their motion for a rehearing.

In rendering its decision in the Atlanta case the Supreme Court stated that the refusal of the Georgia State Railroad Commission to hold that for rate-making purposes physical property must be valued at replacement cost was correct; whereas in the Southwestern Telephone case the court said that contemporaneous reproduction cost must be taken into consideration in fixing rates for public utilities, and in the Bluefield Water case the Court said that the West Virginia Public Service Commission had not given due consideration to replacement cost.

The Atlanta Gas Company's petition also points out that its case was decided by a court of seven justices and

Plans Under Way for Two New Bridges in Portland, Ore.

Bids are to be called for in September on substructures for two vehicular bridges across the Willamette River in Portland, Ore., and about the first of the year plans will be completed and bids will be invited on the superstructures. The funds for these bridges will be provided from county bonds authorized at an election last fall which allotted \$3,000,000 for a new bridge where the Burnside bridge now stands and \$1,600,000 for another bridge about 1½ miles further upstream.

After comparison of steel and concrete designs, concrete was selected for both structures despite the fact that it was the more costly. In the case of the new Burnside bridge the concrete arch design will cost \$104,000 more than a steel structure. This bridge will have a total length of about 3,000 ft. with a 213-ft. double-leaf, trunnion-bascule center span, flanked on either side by a 255-ft. three-rib concrete arch with concrete viaduct approaches. Clearance above low water will be 65 ft. The width will be 86 ft., of which 66 to 68 ft. will be roadway.

The Ross Island bridge will have a clearance of 132 ft. above low water and no draw span will be included. This structure will be 4,000 ft. long, the channel portion consisting of six concrete arches of 270-ft. span with a rise of 90 ft. from springing line to crown. The width will be 54 ft. overall.

Hedrick & Kremers, consulting engineers, are in charge of design and construction on both bridges for the county. Traffic studies were made by J. P. Newell of the city planning commission. The Strauss Bascule Bridge Co. has the contract for the bascule span.

Bids Rejected for Delaware River Bridge Cables

Bids received Aug. 15 by the Delaware River Bridge Joint Commission for Contract No. 8 for the cables of the Delaware River Bridge were rejected because they exceeded the appropriation. Work will be readvertised and another opening held Sept. 19. Only two firms bid, as follows:

Item	Estimated Quantities	Frederek Snares Co., New York		Oscar Daniels Co., New York	
		Unit Price	Amount	Unit Price	Amount
1 Wire cables.....	lump sum	\$2,622,000	\$2,741,000
2 Suspension rope.....	105,000 lb.	\$1.82	191,100	\$1.70	178,500
3 Steel castings.....	1,020,000 lb.	163,200	255,000
4 High tensile bolts.....	100,000 lb.	15,000	25,000
5 Hand ropes.....	lump sum	6,800	7,000
6 Structural steel.....	90,000 lb.	18,000	18,000
7 Cast iron.....	30,000 lb.	3,600	4,500
Total bid.....	\$3,019,700	\$3,229,000

that the other two cases were heard by a full bench. It was Judge Brandeis who handed down the majority opinion in the Atlanta case, and who rendered the minority opinion in the Southwestern Telephone case. In the latter case he stated that he differed fundamentally from the majority concerning the rule to be applied in determining whether a prescribed rate is confiscatory (*Engineering News-Record*, June 7, 1923, page 1010).

In concluding its petition the Atlanta Gas Co. states that this is the first instance in which a company has ever been denied the right to earn rates on the present value of its property.

The bids cover the construction of the two cables of the bridge, together with suspenders, but do not include wrapping of the cables. The cables will be larger than any previously constructed, each one being 30 in. in diameter, and composed of 18,666 separate parallel wires of No. 6 gage, galvanized wire, 0.196 inches in diam. The cables will have a sag of 200 feet, and a length from anchorage to anchorage of approximately 3,560 feet. The cable band castings for attachment of the suspender ropes, the anchorage collar castings and all other cast steel portions are to be of electric furnace cast steel.

World Power Conference Planned for Next Year

British Electrical and Allied Manufacturers Sponsors for London Session

During the summer of 1924 there will be held in connection with the British Empire Exhibition in London a World Power Conference initiated by the British Electrical & Allied Manufacturers Association, Inc., but participated in by many technical and scientific institutions and industrial organizations in Great Britain and other countries. The object of the conference will be to consider how industrial and scientific sources of power may be adjusted nationally and internationally.

The objects of the conference are to achieve by: considering the potential resources of each country in hydro-electric power, oil, and minerals; comparing experiences in the development of scientific agriculture, irrigation and transportation by land, water, and air; conferences of civil, electrical, mechanical, marine, and mining engineers, technical experts and authorities on scientific and industrial research; consultations of the consumers of power and the manufacturers of the instruments of production; conferences on technical education to review the educational methods in different countries and to consider means by which existing facilities may be improved; discussions on the financial and economic aspects of industries, nationally and internationally; and conferences on the possibility of establishing a permanent world bureau for the collection of data.

The conference probably will divide itself into the following sections: Power resources, power development, power application, and the economic and financial aspects of power.

AMERICANS TO PARTICIPATE

In response to invitation for American participation in the conference, twenty or more American engineering, technical and industrial organizations have appointed representatives to a committee of arrangements which has planned an organization with John W. Weeks, Secretary of War and chairman of the Federal Power Commission, as honorary chairman, and O. C. Merrill, executive secretary of the Federal Power Commission, general chairman.

Following conferences in London with Mr. Merrill and J. B. Chailles of Canada, officials of the World Power Conference have agreed upon a tentative program. Participation of all western Europe except Russia and Germany is assured. It is planned to feature a concise statement of the existing situation in each country and to discuss conditions under which capital of one country can be invested in utility enterprises in another. All papers to be presented will be printed in advance so that the entire time of delegates at the meetings may be devoted to discussion. British manufacturers are convinced that they benefit greatly by improving the status of the engineer and a studied effort will be made to make this conference helpful to the engineer.

The organizing director of the World Power Conference is D. N. Dunlap, secretary of the British Electrical & Allied Manufacturers Association.

Engineering Societies

Calendar

Annual Meetings

NEW ENGLAND WATER WORKS ASSOCIATION, Boston, Mass.; Annual Convention, Burlington, Vt., Sept. 18-21, 1923.
INTERNATIONAL ASSOCIATION OF STREET SANITATION OFFICIALS, Chicago, Ill.; Annual Conference, Chicago, Sept. 27-28, 1923.
AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 8-11.
AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 17-20.
AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga.; Nov. 12 to 16.

The American Institute of Architects, Denver Chapter, has given to the library recently established by the Colorado Engineering Council, technical books valued at more than \$5,000. The engineers' library is maintained at the Denver Public Library.

Personal Notes

LESTER L. LESSIG has been made assistant contracting engineer of the Philadelphia office for the McClintic-Marshall Co., with address in the Morris Bldg., Philadelphia. For the past two and one-half years Mr. Lessig has been assistant to the chief engineer of this company.

COL. CHARLES KELLER, who resigned as engineer-commissioner of the District of Columbia in April to investigate the possibility of engaging in hydro-electric work in the West, and who was granted a leave of absence from the Corps of Engineers, has had that leave extended another two months, thus being retained on the active list. Col. Keller is business manager for the El Dorado project being constructed by the Western States Gas & Electric Co.

CHARLES H. ENSIGN, construction engineer of Cleveland, Ohio, and MARK G. SNOW, recently engineer of roadway, track and bridge costs with the Froelich & Emery Engineering Co. on the appraisal of the interurban railways of the state of Michigan for the public utilities of that state, have established offices at 517 National Bank Bldg., Cleveland, Ohio, for the practice of civil, architectural and appraisal engineering, under the name of ENSIGN AND SNOW.

JOHN G. SULLIVAN, consulting engineer, Winnipeg, Canada, is president of a new company organized in that city under the name of the Canadian Engineering & Construction Co., Ltd., which will do general engineering and construction work and which has secured a contract for building 51 miles of high-tension line for the Manitoba Power Commission. The company will act as

consulting, supervising and constructing engineers and in an advisory capacity to railways. Mr. Sullivan has been in private practice in Winnipeg since 1918. Before that he was chief engineer of the Western Lines of the Canadian Pacific Ry. He is a past president of the Engineering Institute of Canada. The vice-president of the new firm is Theodore Kipp, head of the firm of Kipp-Kelly, Ltd., and the secretary is C. A. Monkman who has been with the Manitoba Steel & Iron Co., Ltd.

PERCY CUPPER, state engineer of Oregon for five years and with the state engineering department for some eighteen years, was removed from office August 1, without notice, by the new governor of Oregon and was replaced by RHEA LUPER who has been assistant state engineer for fourteen years. Reasons for the change are ascribed wholly to politics. Mr. Cupper, who has been admitted to the bar, will open an office in Salem, Ore., it is reported, for the practice of irrigation law.

MAJOR JAMES F. CASE sailed August 18 for Montevideo, Uruguay, where he will take up his duties as chief consulting engineer for Ulen & Co., Inc., New York City, in connection with hydro-electric construction works in South America. Major Case has had long and varied experience with work of this kind in the Pacific Northwest and the Philippine Islands, and has reported on properties and projects in Italy, Spain, France, Mexico and Venezuela. As director of public works in the Philippine Islands from 1901 to 1910 he made exhaustive studies of the water-power possibilities of the Islands and in 1918-1922 studied and reported on the principal hydro-electric properties in Northern Italy. He is a Membre d'Honneur des Ingenieurs Civils de France and member of Joint Committee on Co-operation Between International Technical Bodies, appointed by the four founder societies in the United States together with the engineering societies of England, France and Italy.

LIEUT.-COL. WILLIAM B. CAUSEY, who since 1919 has been technical adviser to Austria, has been appointed city manager of Norfolk, Va., at a salary of \$20,000 per year. Colonel Causey was born in Suffolk, Va., 58 years ago. From 1883 to 1890 he was engaged in railway work in various capacities with the Atlantic & Danville R.R., the Suffolk & Carolina R.R. and the Union Pacific R.R. and then for a year was in private practice in Suffolk, Va. Then followed promotions in railway work from assistant superintendent, Milwaukee Division, to division superintendent, Chicago & Northwestern Ry., chief engineer of Elgin, Joliet & Eastern and Chicago, Lake Shore & Eastern Rys. From 1914 to 1917 he was vice-president of the Norwood, White Coal Co., Des Moines, Iowa, and fuel agent for the Buick Motor Co., Flint, Mich. Between 1917 and 1919 he served as captain and major in the 17th Engineers, a railway shop regiment, and lieutenant-colonel, Engineers, U. S. Army, in charge of hospital, camp, warehouse, dock and railway construction at Nantes and other places in Base Sec. 1 in France; in 1919 he was made president of the Allied Railway Mission, at Trieste and Vienna and American member of the Danube River Commission.

C. O. FASS, chief engineer of the New Brunswick Electric Power Commission, has resigned.

R. W. ARMSTRONG has been appointed division engineer of the Northwest division of the Kansas State Highway Commission with headquarters at Concordia, Kan. Mr. Armstrong was formerly resident engineer on federal-aid projects in Doniphan County.

PROF. FRANK P. MCKIBBEN, of Union College, has been appointed a member of the City Planning Commission of Schenectady, N. Y.

E. G. SHIERLEY, who served during the World War as a sanitary engineer in the U. S. Public Health Service, has been appointed sanitary engineer for the city of Los Angeles, Calif., in charge of sanitation and housing problems.

Obituary

WALTER SMITH, for many years a member of the organization of the Atlas Portland Cement Co., died August 1, 1923, at his home in Des Moines, Iowa, after a brief illness.

JOHN C. TEMPLE, hydraulic engineer and for the past fifteen years manager of the Chicago office of S. Morgan Smith Co., died suddenly August 8 in Davenport, Iowa; he was 65 years of age. Mr. Temple at an early age became interested in the hydraulic turbine industry, his father being one of the original members of the firm of Stout, Mills & Temple, Dayton, Ohio, who were among the pioneer water wheel builders of the country. His entire career was devoted to water power engineering and the manufacture and sale of hydraulic turbines and accessories, and covered experience in Philadelphia, New York City and Montreal, also exploration of water power possibilities in Mexico and Central America. He joined the S. Morgan Smith Co. twenty years ago.

THOMAS ELLIS BROWN, for the past twenty years consulting engineer to the Otis Elevator Co., a pioneer in the design and construction of hydraulic and electric elevators, and the originator of the Brown type of bascule bridge, died of heart disease at his home in Morristown, N. J., Aug. 15, after a month's illness. He was 67 years of age. Shortly after graduation from Columbia University Mr. Brown was assistant to Prof. Shunk, of that institution in railway and topographic instruction. Later he became assistant engineer in charge of the design and construction of a part of the Ninth Ave. Elevated structure, New York City. About 1884 Mr. Brown joined the engineering staff of the Otis Elevator Co., becoming its chief engineer. He acted in that capacity until about 20 years ago when he established consulting offices; however, he was retained as a consultant by the Otis company until his death. One of the notable achievements of Mr. Brown was the design and installation of the elevators in the Eiffel Tower, in Paris. The first installation of his bascule bridge was made at Buffalo, N. Y., and was described in *Engineering News* Jan. 16, 1908, p. 51.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Standards Adopted for Tilting Mixers

Joint Committee Agrees On Three Sizes, 3½, 5 and 7 cu.ft.—Name- plate to Show Rating

At a meeting in Chicago, July 30, a joint committee of manufacturers of tilting concrete mixers and contractors agreed upon standards for the equipment under consideration. The following detailed report on the action of the meeting supplements the news article which appeared in *Engineering News-Record*, Aug. 9, p. 244:

1. Standard of Measurement.

(a) The standard of measurement of drum capacity shall be the cubic foot.

(b) The standard for water-tank measurement shall be the U. S. standard gallon.

(c) It is recommended that the question of rating engines and motors be taken up by the Joint Committee on Construction Equipment in conjunction with engine and motor manufacturers.

2. Rating of Mixers.

The size of the mixer shall be designated by a number indicating the nominal rating of the mixer according to its capacity in cubic feet of mixed concrete per batch.

3. Table of Aggregate Proportions.

A standard table of mixed aggregates derived from authoritative sources shall be adopted and published by the manufacturers. This table, based upon 40 per cent of voids in the course aggregate and 3.8 cubic feet of cement per barrel is as follows:

Proportions Of Mix	Resultant Concrete per Bag, Cu.Ft.	Proportions Of Mix	Resultant Concrete per Bag, Cu.Ft.
1-1½-3	3.55	1-2½-4	4.85
1-1½-3½	3.86	1-2½-5	5.13
1-2-3	3.89	1-2½-5	5.47
1-2-3½	4.20	1-3-5	5.83
1-2-4	4.52	1-3-6	6.50

Values taken from Taylor and Thompson's Tables of Aggregate Proportions.

4. Sizes.

It is recommended to mixer manufacturers that two sizes under 7-S be adopted as standard; namely, the 3½ and the 5 cu.ft.; and that sizes below the 3½ be omitted from the standardization program for the present.

5. Standard Table of Batches.

A standard table of batches based upon the table of mixed aggregates provided under Article 3, shall be adopted and published by the manufacturers. This table is as follows:

Proportions Of Mix	Resultant Concrete per Bag Cu.Ft.	Building Mixers					Paving Mixers			
		3½-S	5-S	7-S	14-S	21-S	28-S	Max. No. Full Bags per Batch	13-E*	21-E
1-1½-3	3.55	1	1	2	4	6	8	1	3	6
1-1½-3½	3.86	1	1	1	3	5	7	1	3	6
1-2-3	3.89	1	1	1	3	5	7	1	3	6
1-2-3½	4.20	1	1	1	3	5	7	1	3	6
1-2-4	4.52	1	1	1	3	4	6	1	2	5
1-2½-4	4.85	1	1	1	3	4	6	1	2	4
1-2½-5	5.13	1	1	1	3	4	6	1	2	4
1-2½-5	5.47	1	1	1	3	4	6	1	2	4
1-3-5	5.83	1	1	1	2	4	5	1	2	4
1-3-6	6.50	1	1	1	2	3	4	1	2	3

* Either the 12-E or the 13-E is to be eliminated, depending upon results of a referendum to the A. G. C.

The resultant concrete per bag is based upon 3.8 cu.ft. of cement per barrel and 40 per cent of voids in the coarse aggregate.

Building mixer batches are based upon 1½ gal. of water per cubic foot of mixed concrete.

Paving mixer batches are based upon 1 gal. of water per cubic foot of mixed concrete and upon a maximum operating grade of 8 per cent.

6. Standardization of Mixer Equipment.

(a) The 3½ and the 5 cu.ft. mixers may be equipped with power loaders and water tanks.

(b) Pressure water tanks shall withstand a working pressure of 150 lb. per square inch.

(c) Water connections on the 7-S and under shall be ¾-in. garden hose connections.

(d) Loading skips shall be made with closed ends on the 7-S and under.

(e) Auxiliary hoisting drums may be furnished on the 7-S and under.

7. Shafts, Keys and Keyways.

A. S. M. E. sizes of shafts, keys and keyways shall be used.

8. Safety Devices.

All working parts shall be guarded in accordance with the requirements of state laws.

9. Standard Nomenclature.

The nomenclature of the Concrete Mixer Association, with such additions as may be later approved by the manufacturers, shall be adopted as standard.

10. Name Plate.

(a) A name plate giving the standard rating of the machine and its capacity for different proportions of mix shall be affixed to each machine.

(b) Pending adoption of American Standards, the plate shall state that the machine meets the standard A. G. C. requirements as approved by the Joint Committee of Mixer Manufacturers and Contractors. (Note: A standard plate was adopted.)

(c) Until such time as the Associated General Contractors can take definite steps for approval of batch capacities of the standard mixers each manufacturer shall furnish to the A. G. C. an affidavit stating that the machines comply with the standards and will satisfactorily mix the batches listed on the name plate.

11. Use of Standard Plates.

(a) Manufacturers conforming to these standard requirements shall be allowed the use of the A. G. C. name plate—it being understood that due to manufacturing and competitive condi-

tions it may be necessary for manufacturers to continue their present non-standard sizes—it being further the sense that the manufacture of such non-standard sizes shall be eliminated by Jan. 1, 1925.

(b) After Sept. 1, 1923, any manufacturer bringing out a new size of mixer not in accordance with the established standards, shall forfeit his right to the use of the A. G. C. name plate so long as he departs from the standards, it being understood that mixers larger than 28 cu.ft. and under 3½ cu.ft. are not considered.

Adopt "Corduroy" as Trade Mark

To differentiate the type of traction employed on their revolving shovels, cranes and draglines from other similar types of endless chain tractions Pawling & Harnischfeger, Milwaukee, have adopted as a trade mark the word "Corduroy" worked into the design shown below.

Excavators, the company points out, are called upon to do considerable traveling over soft ground. The first machines, which were mounted on wheels, used mats when operating in, or crossing, soft soil. The mats really amounted to short sections of corduroy road which were transported with the machine. They were picked up from the rear as the machine traveled along and set in front again, a slow process.

P&H Excavators were developed upon the principle of carrying and laying their own corduroy road. The traction consists of an endless chain of steel treads which are, in effect, the logs of a corduroy road since they lie close together and form a path upon which the machine travels. The first machines built by the P&H company had blocks of wood bolted crosswise onto the endless chains of the traction device, and the P&H design, therefore, is described as a Corduroy traction.

Lumber Course, by Mail, Has 3,000 Students

Three thousand students are now enrolled in the free correspondence course in lumber and construction information conducted by the National Lumber Manufacturers Association, and a goal of 6,000 is set for the season's enrollment. The purpose of the course is to give lumber merchants and others a background of knowledge of their material and its application in construction. The course consists of sixteen chapters on such subjects as merchandising, technical and physical properties of lumber, planning and designing, estimating and rules for taking off quantities, figuring stresses and sizes, shingles, wood preserving, heavy timber mill construction, blue print reading, and commercially important trees.

The student requests one chapter at a time from the National Lumber Manufacturers Association, International Building, Washington, D. C., or Conway Building, Chicago, Ill., and after having reported studying successfully the sixteen chapters receives a certificate of graduation.

Contractors' Vote Favors 21-S Concrete Mixer

Of 132 Ballots Cast 83 Indicate a Need for the Three-Quarter Yard Size on Construction

BY a vote of 83 to 49 members of the Associated General Contractors of America have gone on record in favor of retaining as one of the standard sizes the 21-S concrete mixer which was the subject of a ballot sent out after the meeting in Chicago, June 27-29, of the Joint Committee on Construction Equipment (see *Engineering News-Record*, July 26, p. 160). Some of the members gave the following reasons in explanation of their vote favoring or opposing the 21-S size:

IN FAVOR

This size fits more jobs than any of the larger sizes.—Yakima Paving Co., Yakima, Wash.

Would give 21-S preference over 14-S or 28-S. Have been using for 12 years on our larger building operations.—Lundoff-Bicknell Co., Cleveland.

On work requiring rich mixtures 21-S is a size of value; many such jobs are overplanted with a larger mixer.—F. L. Cranford Co., Brooklyn.

Three-quarter yard mixer most desirable for work on buildings in general.—Henry Ericson Co., Chicago.

I prefer 21-S because more easily handled, costs less and is more economical. It is large enough for any ordinary building construction.—W. T. Hadlow, Jacksonville.

21-S considered more flexible than 28-S; operating satisfactorily and arguments do not warrant discontinuance.—John J. Kane & Co., El Paso.

21-E paver fits in more economically and is better adapted to general run of work than other sizes.—Crissey Constr. Co., Johnstown, Pa.

21-S is most convenient size for moving and installing; large enough for big jobs and not too large for medium size jobs.—H. B. Sproul Construction Co., Scranton.

While 28-S will do the work, its weight makes transportation and installation a serious matter. We should be very sorry to see 21-S go—we use it constantly.—Arthur S. Bent, Los Angeles.

We find 21-S city jobs, where most times available space for plant is limited. We use 7-S, 14-S and 21-S, but no 28-S.—Walbridge & Aldinger Co., Detroit.

OPPOSED

A job justifying anything larger than a 14-S is suited to a 28-S.—Hogan & Humphrey, Little Rock, Ark.

Three-quarter yard mixer too large for a side loader. If large mixer is desired on large work, fed from bins and hoppers above, a 1-yard mixer is preferable—for medium sized work and under a one-half yard mixer does the work nicely.—E. L. Scheidenhelm, Chicago.

On a job requiring large mixer, 28-S is just as economical even when operated at three-quarter yard capacity, and, on a small job, 14-S is sufficient.—Wolverine Engineering Co., Mason, Mich.

We use 21-S least of all. On large jobs have not used 21-S since 1920.—John J. Turner & Sons, Amsterdam, N. Y.

Business Notes

PIONEER INSTRUMENT Co., Brooklyn, N. Y., has purchased the business of Brandis & Sons, Inc., including their factory and equipment. The latter company has made engineering and nautical instruments since 1872, while the Pioneer company manufactures aircraft instruments exclusively. Each organization will continue the sale of its own product. Their manufacturing facilities will be combined, however, and operated as one plant. William F. and Henry A. Brandis will continue as president and vice-president of Brandis & Sons. Both companies will occupy the Brandis building at 754-758 Lexington Ave., Brooklyn.

Equipment and Materials

Furring Clip for Wire Mesh

For holding wire mesh at the proper distance from surfaces to be plastered or covered with stucco, a simple furring clip is being manufactured by the

G. L. W. Manufacturing Co., San Diego, California. The clip, as shown in the accompanying illustration, consists of a bent strip of galvanized metal which is hung over the wire and fastened with a four-penny nail.

Track Shifting Car

A machine for shifting track laterally or raising it vertically has been placed on the market recently by the Lake Superior Loader Co., Duluth, Minn., and is shown in the accompanying view. This machine is adapted for shifting dump-car tracks on railway or

other construction, coal and ore stripping and similar work. In fact it is the development of a machine which has been in use for some months in shifting track on the waste dump of an iron ore mine in Minnesota. The four-wheel car, 10 x 7 ft. in size, has at the center a 7-ft. vertical spud raised and lowered by a rack and pinion, and fitted with a broad shoe on the bottom. The pinion mechanism has a lateral travel across the floor of the car. In operation, four rail tongs attached to the car frame are clamped to the rails.

The spud is inclined in the direction the track is to be shifted and is racked down so as to lift the car, carrying with it the rails and ties. Owing to the inclination of the spud the whole structure slides laterally until the ties again rest on the ground. The tongs and spud are then released and the car is moved forward about two rail lengths to repeat the operation. A gasoline engine drives the car and operates the spud gear. The machine weighs about 2½ tons. It is stated that this machine with one man has replaced eight men in a track gang engaged in shifting track on one stripping work. Track can be raised in the same way (without shifting it laterally) for ballasting, tie renewals or raising grade.

Oil Burning Tool and Surface Heaters for Asphalt Repairs

Improvements in its oil-burning tool and surface heaters for the repair of asphalt pavements, originally introduced about five years ago, are announced by the Chausse Oil Burner Co., Detroit. The tool heaters, illustrated in the accompanying photograph, are now equipped with Timken bearings, steady rests and a new type of burner. Rubber tires may be added to make possible

more rapid and noiseless transportation when hauled by motor truck. Fuel tanks provide sufficient kerosene or distillate for two 8-hr. days of continuous burning at maximum temperature. The tool heaters will bring fourteen or fifteen cold tools up to proper temperature in 15 min. and provide space for heating three buckets of asphaltic cement, so that two gangs can work with one machine. The burners generate maximum temperature in 5 min., eliminating the

necessity of building up coal or wood fires long in advance of the use of the machine. With the oil fuel employed there is no nuisance or danger from smoke, sparks or ashes.

The surface heaters are made in two sizes; one to cover 2 sq.yd. to work up to street car tracks without interfering with car movement, and the other to cover 4 sq.yd. Both machines are mounted on springs to facilitate trans-

portation. With these heaters, the manufacturer states, it has been found possible to melt down old asphalt to a 1-in. depth in 4 to 5 min.

New Type of Light Gas Car For Narrow-Gage Railway

A new type of self-contained gasoline-driven railroad motor car has been supplied to the Nevada-California & Oregon Ry. Co. by The A. Meister Sons

Co. The cars are built to operate on 36-in.-gage track. On a test run of 520 miles one of them averaged 11 miles to a gallon of gasoline and less than one pint of lubricating oil. The average speed was 35 m.p.h. and the maximum 55 m.p.h. The car carried 28 passengers and negotiated grades of 2½ per cent. The car weighs 8 tons.

The length of the car is 32 ft. and the width 7 ft. The distance between the rear drivers and the center of the bolster bar on the front truck is 20 ft. The height from top of rails to center of roof is 8 ft., and from top of rails to floor of car 14 in. These cars are operated by one man, from the front end of car. They are equipped with 4-cylinder motors, Arcola hot water heater system, and electric starter, generator, lights and horn. There is absolutely no noise in the car body, this being due to the rubber cushion springs. By placing the motor to the rear of the driving wheels, all revolving parts in front of the rear axle have been eliminated, thereby permitting a very low-hung car and eliminating all motor noise, smoke, grease and gasoline odor from the inside of the car.

Practically all vibration has been eliminated by suspending the motor on coil springs directly over the rear axle, on one end of a sub-frame. This sub-frame has a swivel bolster bar built in the main frame at one end so that it will turn at curves, thus eliminating flange wear and relieving side thrust.

The car is equipped with a Westinghouse accumulator, taking air from the front cylinder, this air being used for sanders only. The breaking power is 175 per cent.

Similar cars are built in all gages from 2 ft. up.

Gasoline Dipper Shovel

A gasoline-driven power shovel operated entirely with gears and shafts and known as the O. S. Dependable, is announced by the Orton & Steinbrenner Co., Manufacturers of cranes, shovels, and buckets, of 608 So. Dearborn St. Chicago. The positive gear drive, the feature of the O. S. Dependable, is simple and the number of parts few.

At the bottom of the boom connection is a shaft carrying double steel bevel gears and bronze friction clutches. This shaft is concentric with the pivot of the boom and consequently independent of its position. The boom can be used at any angle to suit the exigencies of the work.

Along the boom is a steel shaft carrying two bevel pinions, one meshing at the bottom with the gears on the horizontal shaft, and the other at the

top meshing with gears on a counter-shaft located about half way up the boom. This latter shaft carries a brake and "slip friction," and is geared directly to the cast steel rack on the dipper stick. With this method, a minimum number of levers are required.

The hoisting mechanism is the same type as has been used in the locomotive

cranes built by the Orton & Steinbrenner Co. for fifteen years. The simplicity of parts is also of great advantage in converting the shovel into a clamshell outfit, dragline, or skimmer rig. The power is supplied by a heavy duty 4-cylinder "Climax" motor. Another exclusive feature of the machine is the flexible crawling tread.

Publications from the Construction Industry

Grab Bucket Cranes—PAWLING & HARNISCHFEGER CO., Milwaukee, Wis., has just issued a new bulletin covering its complete line of traveling grab-bucket cranes and monorail hoists. This bulletin has 32 pages and is freely illustrated with pictures of the various kinds of grab-bucket equipment and many views showing its installation in various industries.

Electrical Development—GENERAL ELECTRIC CO., Schenectady, N. Y., has issued to its stockholders a 34-p. booklet reviewing the 30 years' history of the company from its foundation in 1892 to 1922.

Air Compressors—**INGERSOLL-RAND** Co., New York, has issued a new 35-p. illustrated bulletin describing its medium and large sized steam-driven air and gas compressors built in a number of types and sizes. The capacities of the standard two-stage machine for 100 lb. discharge pressure range from 246 to 4150 cu.ft. per minute piston displacement. Single-stage compressors are built for furnishing 50 lb. discharge pressure. A feature of the equipment is the steam valve gear consisting of completely balanced piston valves with riding cut-off valves telescoping within the main valves. An automatic cut-off governor maintains constant air pressure, regulates the steam cut-off and adjusts the speed of the compressor to the demand for air.

Lumber in Architectural Construction—**SOUTHERN PINE ASSOCIATION**, New Orleans, has published in the form of a 16-p. booklet recommendations for the use of Southern Pine lumber in architectural construction, covering grades and sizes in accordance with the association's standards which have been approved by the Louisiana Chapter, American Institute of Architects, The General Contractors Association of New Orleans, and the New Orleans Retail Lumber Dealers.

Turbine Pumps—**LAYNE & BOWLER** Co., Memphis, Tenn., describes and illustrates its turbine pumps and well screens for railroad, mining, industrial, municipal and irrigation service in a 64-p. catalog just issued. Details are given regarding the Layne shutter screen for large bore wells, and also the Keystone wire wrapped screen manufactured of perforated pipe covered with a spiral brass winding. One chapter of the text is devoted to the development of underground water supplies. Complete data are given regarding the company's vertical turbine well pump and a number of typical installation views are shown.

Gasoline Motors—**WAUKESHA MOTOR** Co., Waukesha, Wis., in a 32-p. illustrated pamphlet, illustrates and describes its industrial power unit consisting of a 4-cylinder gasoline engine in sizes of from 20 to 45 hp. The unit is housed with sheet metal, is portable, and is recommended for use in operating sawmills, hoists, pumps, stone crushers, concrete mixers, air compressors and road machinery. The power take-off is a housing that can be attached to the flywheel housing of any Waukesha motor.

Waterproofing—**GENERAL FIREPROOFING** Co., Youngstown, Ohio, in the sixth edition of its "Waterproofing Handbook" describes methods and materials for waterproofing concrete and all forms of masonry, both above and below grade, and protecting finished surfaces of wood, plaster, concrete or metal against water, wear and stains. The volume comprises 72 p., illustrated, divided into five parts dealing with substructural waterproofing, superstructural waterproofing, cement and wood floor preservation, technical paints and coatings, and the company's waterproofings and preservatives. The text is supplemented by a number of photographs and drawings indicating waterproofing details.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Freight Movement for Half Year Greatest in Railway History

The railroads of the United States during the first six months this year carried the greatest freight traffic for any corresponding period in their history, according to tabulations just made by the Bureau of Railway Economics, based on reports filed by

Bookings of Steel Castings

July bookings of steel castings, based on reports received by the Bureau of the Census of the Department of Commerce amounted to 52,066 tons, as against 84,878 tons in June, representing two-thirds of the commercial castings capacity of the United States. The following table shows the bookings

BOOKINGS OF COMMERCIAL STEEL CASTINGS

Month 1923	Total		Railway		Specialties		Miscellaneous Castings	
	Net Tons	Per Cent of Capacity	Net Tons	Per Cent of Capacity	Net Tons	Per Cent of Capacity	Net Tons	Per Cent of Capacity
January.....	100,605	103.8	47,879	125.0	52,726	90.0	0	0
February.....	90,152	93.0	39,845	104.0	50,307	85.8	0	0
March.....	143,564	148.2	76,409	199.5	67,155	114.6	0	0
April.....	90,968	93.9	39,610	103.4	51,358	87.6	0	0
May.....	89,493	92.4	38,788	101.3	50,705	86.5	0	0
June.....	84,878	87.6	42,773	111.7	42,105	71.9	0	0
July*	52,066	53.7	16,741	43.7	35,325	60.3	0	0

* Two companies with a capacity of 785 tons per month on miscellaneous castings now out of business.

the carriers. Measured in net ton-miles, it amounted to 225,435,608,000, an increase of 7 per cent over the corresponding period in 1920 which had marked the previous record.

TON-MILEAGE FIGURES

Compared with the first half of last year when, however, freight traffic was reduced by the miners' strike which began on April 1 and continued until late in the summer, the total net ton-miles for the first six months this year was an increase of more than 32 per cent. In the Eastern district, which was especially affected by the miners' strike, there was an increase over the first six months last year of 37.6 per cent in freight traffic, while the Southern district reported an increase of 29½ per cent. In the Western district the increase was 26 per cent.

For the month of June alone freight traffic amounted to 38,000,994,000 net ton-miles, or an increase of nearly 31 per cent over the same month last year when the miners' strike was in progress. The Eastern district showed an increase of more than 46 per cent in freight traffic, the Southern district 14 per cent and the Western district 17 per cent. Freight traffic in June this year has only been exceeded twice during that month in previous years, once in June, 1917, and again in the month of June, 1920.

AVERAGE CAR MOVEMENT

The average movement per freight car during the month of June was 28.3 miles per day. This was the highest average for any June since 1917 when it was exceeded by 0.1 mile. It also was an increase of 4.4 miles over June last year, and 6.3 miles over June, 1921, but a decrease of 0.3 mile under the daily average for May this year. Every increase of one mile in the average movement of a freight car is equivalent to the addition of 100,000 freight cars to the country's transportation facilities without any increase in capital expenditures.

The average load per car in June was 28.2 tons. This was not only an increase of 0.2 ton over the average for May this year but was the highest average for any June since 1917, except in 1918 when the average was 28.3 and in June, 1920, when it was 28.9.

of commercial steel castings for the past seven months by 65 identical companies, with a monthly capacity of 96,900 tons, of which 38,300 tons are usually devoted to railway specialties and 58,600 tons to miscellaneous castings.

Industrial Employment in July

The U. S. Department of Labor, through the Bureau of Labor Statistics, presents the following preliminary figures concerning the volume of employment in July, 1923, from 6,739 representative establishments in 51 manufacturing industries, covering 2,353,258 employees whose total earnings during one week in July were \$61,174,094. The same establishments in June reported 2,396,012 employees, and total pay rolls of \$64,176,205. Therefore in July, as shown from these unweighted figures for 51 industries combined, there was a decrease under June of 1.8 per cent in number of employees, a decrease of 4.7 in total amount paid in wages, and a decrease of 2.9 in average weekly earnings. This decrease in employment, the first appearing in this series of reports since April, 1922, is largely a seasonal one.

Increases in rates of wages for the month ending July 15 were reported by 302 establishments in 48 of the 51 industries covered. These increases averaged 8.5 per cent and affected 31,829 employees, or 35.3 per cent of the employees in the establishments concerned, and 1.4 per cent of all employees in the 51 industries.

Forty-one industries out of 51 show decreased per capita earnings in July as compared with 27 out of 50 in June.

Freight Cars in Need of Repair

The railroads of the United States on Aug. 1 had 189,014 freight cars or 8.3 per cent of the total number on line in need of repair. This was an increase of 393 over the total number in need of repair on July 15, at which time there were 188,621 or 8.3 per cent. Compared with the number on July 1, it was a decrease of 1,397. Of the total number on Aug. 1, this year, 144,566 or 6.3 per cent of the number on line were in need of heavy repair, an increase over the number in need of such repair on July 15 of 1,285.

Lumber Movement Declines

The nation's lumber movement declined noticeably during the week ending Aug. 11, says the National Lumber Manufacturers Association, as reflected by reports from 382 of the larger commercial sawmills as compared with reports from 406 mills for the preceding week. Shipments fell off about 15 per cent, new business about 10 per cent, and production about 7 per cent. With 122 mills reporting as against 131 for the week before un-filled orders of West Coast mills decreased from 320,039,832 ft. to 305,-

893,356 ft.; and 132 Southern Pine Association mills show a decline in the order file from 228,868,185 ft. to 218,769,525 ft.

For all the reporting mills shipments were 82 per cent and orders 78 per cent of actual production; for the Southern Pine mills these percentages were 95 and 81, and for the West Coast mills 85 and 98. Of the whole number of reporting mills 343 have an established nominal production for the week, in reference to which actual production was 102 per cent, shipments 88 per cent, and orders 85 per cent.

Wholesale Prices in Italy Up

Wholesale prices in Italy have notably increased during the past year, according to index numbers compiled by the Chamber of Commerce of Milan. In June, 1922, taking average prices for 1913 as 100, the general index stood at 504.48, and in June, 1923, it had risen to 539.24. The group showing the largest increase is textile materials, which have risen from 556.44 to 653.91. Minerals and metals have also increased considerably. Food products show a further increase from 549.05 to 564.66.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual biddings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Aug. 2; the next, on Sept. 6.

Steel Products:

	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal
Structural shapes, 100 lb.	\$3 64	\$4 00	\$4 20	\$3 40	\$3 55	\$4 20	\$3 60	\$4 10	—\$4.00
Structural rivets, 100 lb.	4 40	4 75	4 90	3 75	4 25	5 40	5 00	4.75	6.00
Reinforcing bars, $\frac{3}{4}$ in. up, 100 lb.	3 54	—3 50	3 80	3 20	3 45	3 85	3 65	4.10	—3.90
Steel pipe, black, $\frac{3}{4}$ to 6 in. lap, discount.	44 $\frac{1}{2}$ %	52 $\frac{1}{2}$ %	45%	47%	53-5%	36%	33.2@42.2%	40%	47.43
Cast-iron pipe, 6 in. and over, ton.	62 30	56 00	63 00	60 20	60 50	69 00	62 00	70 00	60 00

Concreting Material:

Cement without bags, bbl.	2 70@2 80	3 03	2 25	2 20	2 50	2 84	2 63	2 90	2 25
Gravel, $\frac{3}{4}$ in., cu. yd.	1 75	1 90	2 38	2 00	1 85	1 90	2 15	1 25	1 50
Sand, cu. yd.	1 25	1 24	1 89	2 00	1 25	1 00	1 50	1 25	1 25
Crushed stone, $\frac{3}{4}$ in., cu. yd.	1 75	2 00	2 83	2 00	2 25	3 50	2 15	3 00	1 90

Miscellaneous:

Pine, 3x12 to 12x12, 20 ft. and under, M.ft.	53 00	40 00	52 25	56 50	42.50@43.75	42 75	41 00	28 00	70 00
Lime, finishing, hydrated, ton.	18 20	22 50	22 00	20 00	25 50	24 00	22 00	24 00	21 00
Lime common, lump, per bbl.	3.00@3 25	1 50	2 35	1 50	1 50	2 70	2 10	2 80	10 00
Common brick, delivered, 1,000.	20.00@21.00	12 00	13 10	11 00	17@19	12 00	15 00	13 00	16 50
Hollow building tile, 4x12x12, per block.	Not used	102	115	.0724	.0816	.06511
Hollow partition tile 4x12x12, per block.	1573	102	115065	.108	.11
Linseed oil, raw, 3 bbl. lots, gal.	—98	1 08	—1.14	—1.12	—1.04	1.25	—1.18	.86	1.26

Common Labor:

Common labor, union, hour.	75	35	50@.55	.55
Common labor, non-union, hour.30	.30@.50	.82 $\frac{1}{2}$	— .50@.55	.35@.50	.50	.50@.62 $\frac{1}{2}$	+.35@.40

Explanation of Prices.—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given; 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. Labor—Concrete laborers' rate, 93c.; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu. yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5 $\frac{1}{2}$ x 8 x 11 $\frac{1}{2}$. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 97.75). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.43; 6-in., \$119.

Few Price Changes Since Last Week

In the last few months the price changes have been of small consequence. This week lumber and brick are a trifle softer in New York. Linseed oil continues to decline in a number of cities. Steel is down in Montreal. These are local fluctuations that tell nothing significant.

St. Louis unions of bricklayers, according to *Engineering News-Record's* correspondent, have informed the contractors that, effective Nov. 1, 1923,

the rate shall be \$1.75 per hour—an increase of 25c. At present bricklayers and stone masons are receiving bonuses that with wages amount to about \$1.75 per hour. Carpenters were recently granted an increase of 25c., to \$1.50.

July building permits in 270 cities aggregated \$243,004,821. This is a high normal value for this season of the year and indicates that despite a very high cost level much building is still being planned. The Eastern states

report value of permits in July as 23.6 per cent over July, 1922, and a decline of 3.2 per cent from June of this year. Central states showed a very small increase over July a year ago and a still smaller loss from June of this year. Permits in the Southern states fell off about 10 per cent. The Pacific Coast states reported an increase of 42 per cent over last year and a decline of 17.5 per cent from June of the present year.

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

E. J. MEHREN, *Editor*
FRANK C. WIGHT, *Managing Editor*

Volume 91

NEW YORK, AUGUST 30, 1923

Number 9

Their Appointed Rounds

OVER the portal of the general post office building in New York City is carved a sentence which, possibly because of the felicity of phrasing, has been credited to Woodrow Wilson: "Neither snow, nor rain, nor heat, nor gloom of night stays these couriers from the swift completion of their appointed rounds." When these words were written the airship was little more than a county fair attraction, but how aptly they convey the spirit of those pioneer planes which last week carried the mail across the continent in less than 27 hours. Step by step the world progresses and each tiny movement forward seems so insignificant, until with time we find ourselves in new countries with new landmarks and new conditions. Thus will it be with air transportation; first a toy, then a weapon, still later an experiment for the rich and the curious, before long, as the world counts time, the airship will be a potent factor in transportation.

Traffic for Group Study

ANNOUNCEMENT has been made that the American Bar Association at its next annual meeting is to take up the problem of traffic congestion with a view toward suggestions of legal means of relief. This is an excellent idea. The proposals for congestion improvement involve many nice legal questions, such for instance, as the right of restriction of types of traffic and the redress to ground-floor owners for possible damage by second story streets, to say nothing of the limits to the police power in this new problem. Engineers, however, have much closer interest in traffic control and their societies could well take a leaf out of the lawyer's book. The American Society of Civil Engineers could find no more pressing or interesting subject for one of its annual meetings.

New Cement Possibilities

GRADUALLY emerging from the obscurity of the laboratory and the study the quick-setting high-strength alumina cements are beginning to take on practical importance. The review of their development in Europe by E. C. Eckel, given on another page of this issue, indicates that over there they are beginning to be taken seriously by construction men, which foreshadows a similar progress on this side of the ocean. On account of the nature of their constituents—and especially the concentration in occurrence of the alumina clays that they require—these new cements will never seriously rival the portlands for ordinary construction work. It is obvious, however, that their proved high early strengths make them of the greatest value in certain emergency works where time is the essential quality in completion. For city street work, grade crossings, water pipe repairs, and many easily noted cases, these new cements would be worth the high

price they doubtless will require. So far, their other virtue—that is increased safety in saline exposure—is not so well proved, but if proved that too would make them in demand. Mr. Eckel's article intimates an interest in commercial production of the alumina cements in this country. Much remains to be studied in the behavior of these cements, but in view of their promised value, engineers and constructors will hope that the tests and studies now being made will show them to be commercially feasible.

Detours Versus Half-Roads

PROBABLY no car owner will arise to defend detours. They compel him usually to travel a longer way over ill-kept roads whose marking is generally just clear enough to keep him unsure of his course. The detour indeed is generally damned. To avoid it the practice of building only one side at a time has been developed in paving busy roads. By this procedure one half of the road is theoretically always open to traffic. Until one considers it, this practice seems to have very decided advantages over detours. With a little thought, however, and particularly with a little experience in traveling half-roads, there comes the realization that they are one-way routes, that they put a snail's pace on traffic and that they require very cautious driving to clear the construction operations on one side and the ditch on the other side. Indeed contractors can cite more than a few instances when they have had to reset side forms and restore other finished work because a nervous driver in avoiding the Scylla of the side ditch has risked the Charybdis of an irate foreman of form setting. There is no freedom indeed from more serious disaster. The collision near Nyack, N. Y., on Aug. 9, of a motor bus with the boiler of a paving mixer, which resulted in the death by scalding of six of the bus passengers, is an instance to the point. Truly, this was an extraordinary occurrence but it indicates what can happen. Overturning and slewing are the more ordinary risks run by the user of the half-road. They are real hazards and where the engineer and contractor have the alternative of a good detour they should give it careful consideration. Paving half at a time is by no means a universal remedy of the detour evil in road construction.

Making It Work

JUST how many sewage-works in this country do more than provide a mental protection to the citizen and a buffer for the administration against complainants downstream? Not many years ago an Eastern consulting engineer journeyed through the Middle West in winter to see what the best and some of the average plants were doing. Practically every one he visited was out of commission or producing a decidedly poor effluent. Recently state board of health officials have effected some improvements but at the great

majority of small plants there is still much to be desired. Sludge beds are rarely used, reliance being placed on a fortuitous flood which will enable the operator to dump the sludge at the crest. Holes are punched in the beds for the easy passage (by-passage) to the effluent line. Tanks are not cleaned until the passage ways become no more effective than an enlargement in the trunk sewer. A refreshing exception to the above condition was noted in these pages last week, where the mayor of Newton, Kansas, decided to make the plant work and to overcome the difficulty of foaming over the gas vents of the Imhoff tank. Until engineers got to building the vents high and wide, spewing over the top was the rule, excused by the assertion that the foaming would stop when the "plant gets older and better seeded." The way to prevent misuse, non-operation or careless control of sewage-works is to provide better technical supervision, under the direction of state authorities or, better still, by retaining the engineer who designed the plant. Let him make it work.

Joint Operation of Bus and Trolley

FOR nearly a month a large part of the great state of New Jersey, and all of its large cities, have been without street cars. Not so many years ago this would have been an unbelievable situation. Today, thanks to the automobile and the motor bus, business is proceeding with at least superficial regularity and the inconvenience to the public, while doubtless great, has brought forth no wave of protest which a dozen years ago for a similar condition would have forced some kind of trolley service. The situation which has arisen and the tentative moves toward its solution are so indicative of what may be expected before long in street transportation elsewhere that they are worthy of examination.

The Public Service Corporation of New Jersey, in addition to an enormous power and light business, has a practical monopoly on the street railway systems of northern New Jersey, especially in the metropolitan district, which includes the large cities of Newark and Jersey City. For a number of years it has been in the usual controversies with employees and with the Public Utility Commission trying on the one hand to restrict increase in wages and on the other hand to gain increase in fares. It has been operating for some time on an eight-cent fare basis, with one-cent transfer privileges, and with what is generally conceded to have been an exceptionally low wage scale. Matters were brought to a head on the first of August by a complete strike of the employees for higher wages. The company met the strike by the unusual method of shutting down all street car service. No attempt whatever was made to enlist new employees or to operate with such help as could be diverted from other branches of the service. Northern New Jersey was without street cars.

It so happens, however, that this section of the state has been exceptionally well served with motor buses; in fact, it is to these buses that the company ascribes a large part of the difficulties of the railway. Not only were many roughly paralleling bus lines established, but those streets on which were run the busiest and most profitable car lines were taken as bus routes and thus, the railway claims, the buses skimmed the cream of the traffic, running for the most part on a five-cent fare basis. Immediately upon the cessation of the street car service, additional buses began to run, short time

licenses were issued, municipal buses of the city of New York were loaned, and private automobiles called into service. So for three weeks the communities went about their business hampered, to be sure, but at least getting back and forth in fair fashion.

Finally, the Public Utilities Commission ordered the railway to restore service and their order was answered by a proposition which marks an interesting point in city transportation development. The railway agreed to restore service only after the acceptance of the proposal which has five main features: (1), the purchase by the railway of all competitive buses at present fair physical value, the railway thereafter to operate both bus and street car systems, as will best serve the public in the judgment of the Public Utilities Commission; (2), the refusal by the cities and the commission of any further competitive bus licenses or franchise; (3), the increase of wages asked by the employees; (4), the acceptance of a certain disputed valuation of the entire railway property by the Public Utilities Commission, and (5), the establishment of a seven-cent general fare for both bus and street car. This proposition was accepted by the employees, but the utilities commission balked on the acceptance of the valuation proposal and on the proposition that the railway could make terms before restoring service. In the matter of the competitive buses a hearing is to be held.

The Public Service Corporation is not loved in New Jersey. Whether justly or not, the people distrust it and welcomed the competition that the buses gave. The general trend of opinion in the state, therefore, would probably be unfavorable to any scheme which would establish for the corporation the natural monopoly in city transportation which their proposal frankly states is inevitable if proper service is to be given. On the other hand, the situation which has developed points toward some such solution as the company proposes. It so happens that the bus development in this section has been so great that the controversy here has arisen somewhat sooner than it has in other parts of the country, but it is merely a feather in the wind to show which way the trend of city transportation is going. Sooner or later a similar situation is bound to arise in practically every congested area. The bus, on account of its flexibility of service, is bound to become a serious competitor of the street railway. On the other hand, the street railway is long established. It has been given certain privileges by the public, in return for which it has expended a vast amount of money, looking toward a long time return. It is not just and, in all probability, it is not legal that the public now should take advantage of the changed conditions, which neither the public nor the railway could have foreseen twenty years ago, to permit another type of transportation to arise and destroy, as it inevitably will destroy if not regulated, the investment of the street railways. The way out seems to be that suggested in New Jersey, that is, the taking over of the competitive bus lines by the street railway, and the operation of the two jointly to the best service to the public.

The advantages of street cars over buses and those of buses over street cars are fairly obvious. They need not be argued. What people are interested in is the best service and not the service of one to the exclusion of the other. They must be operated jointly and effectively and, from an engineering point of view, such operation can best be conducted under one head. There are in-

dications that the trouble in New Jersey is deeper than the mere question of bus versus street car, that the direction of the company has seized upon this crisis to put over its own idea of valuation. Probably the utilities commission will not permit any such solution of the difficulty. But if the corporation is in earnest about its street car trouble, it is to be hoped that the commission will be able to adjust the valuation difficulties in such fashion as to permit the monopoly control of the bus and street railway, so that we can have tested the experiment of this type of street transportation operation. Unfortunately, the public is not today as sure that the commission regulation of transportation will insure as good service as will competition, but it seems only fair that the theory should be tried out. The commission has the opportunity now to gain agreement to some arrangement with the railway company whereby the railway will be permitted to show the public how good service it can give by joint operation and in which, also, the commission will have full power to maintain proper service.

An Experiment Worth Trying

ENGINEERS and engineering societies use up a great deal of useful time discussing professional ethics, but they take very little real action which will lead to an improvement in practice. Codes continue to be written and interpreted as generalities, but specific cases in violation are either shrouded in the cloak of anonymity under which the offenders are invisible, or they are used merely as text upon which are written virtuous homilies. Last spring, for instance, an effort was made by the Board of Direction of the American Society of Civil Engineers to inaugurate a more personal application of code violations, but the conservative view characteristic of that society continues to prevail and the impersonal application of ethics remains as before. One can well recognize the difficulties in a more strenuous treatment of this ethics problem, but it is hard to escape the impression that the delicate way in which most societies handle code violations put most of the members in the position of fearing to cast the first stone. Some day some society is going to have the force and courage to take up the situation more vigorously. From that time professional ethics in engineering will begin to be elevated.

Just at present two specific cases of a practice in violation of code offer a suggestion as to how such things might be treated. Each of these cases is an illustration of the way too many cities are going about getting engineering service. In the first, the Board of Water Commissioners of a certain Eastern city, sent out letters to a number of engineers inviting them to submit a proposition covering a complete engineering report on a proposed water supply for the city. The details of the information required were supplied and the engineers were asked to bear in mind that the city wanted the best solution of the water problem and to furnish bids to cover the cost of making the investigation and of preparing plans in shape for decision by the State Board of Health. Thirteen bids were received on this advertisement and the contract awarded on a lump sum basis for the engineering work of investigation and for the engineering work of construction, without regard to the total amount of work that might be required either in investigation or construction.

In the second case, a certain city advertised for competitive sealed proposals from "experienced engineers for preparing preliminary plans and specifications and furnishing estimates of the cost for a modern power plant." The bid was asked as a lump sum and, in addition, engineers making the bids were asked to furnish a bond "for such engineering service." No indication was given as to the use to which such a bond would be put, but it is quite probable that it would be used by the authorities to assure the tax payers that they were receiving proper service and advice.

Both of these are illustrations of a common enough practice. Obviously it is in violation of a proper code of engineering ethics. Probably it is not illegal, but it cannot tend to good engineering because the extent and cost of a true professional investigation cannot be estimated. The consequence is a chance of lower standard of work and the selection of engineers who are willing to cut prices, but whose professional equipment cannot be guaranteed. It is not only detrimental to the engineering profession, but it is dangerous to the community.

The practice, however, will not be cured by individual complaint nor by society generalizations. That has been proved. There have been many such complaints and many such generalizations and the practice continues. It would certainly be an experiment worth trying for some society which has cognizance of a similar performance, and such performances are continually available, to attempt a new line of action. As soon as a city makes public such an offer let the society or the local chapter thereof take a page in the local newspaper noting the case and reviewing the reasons against it. This advertisement, of course, must be dignified and sufficiently authenticated to relieve any of the members of the society from the charge of self interest. It should not be published until after an argument by the society with the city officials had proved unavailing. If the city persists in its advertising after the notice by the engineering society and accepts bids, let the society then issue a second advertisement in which the names of the engineers who have bid are specifically mentioned with appropriate comment regarding the possibilities and probabilities involved in the whole transaction. If there is anything at all in the force of public opinion, or if there is any such thing as public respect for the engineering profession there will be few city administrations that would dare to go through with this advertising for engineering services after such a campaign by the representative engineers of the community.

It is recognized that any local society will probably contain in its membership certain of the engineers who will participate in such a competition. It is the privilege of these engineers to vote in open meeting on the desirability of the society entering into an open campaign against the practice of bidding for engineering services, but having spoken they have no redress in law or in ethics for public chastisement by their professional brethren provided always that these brethren have not themselves in the past participated in similar practices and are thereby disbarred from criticism.

Such a procedure would be in definite opposition to anything that has ever occurred. There should be somewhere, however, a group of engineers with sufficient courage to take up such a definite stand in specific defense of what every engineer will admit is a proper attitude of mind.

Building New Argentine-Chilean Transandine Railway

New Transandine Line Has American Viaducts and Equipment—Maximum Grade 2.5 Per Cent—Uses Switchbacks and Spirals—Tunnels, Cut-and-Cover Work—Summit 14,681 Ft.

By RICHARD F. MAURY
Chief Engineer of the Salta-Chile Extension,
Argentine State Railways

A SOUTH AMERICAN railway development which should mean much to the United States and which will probably cause important changes in trade routes, besides opening a rich section of country, is the Salta-Chile extension of the Argentine State Railways, now under construction, to connect the existing railway system with the Pacific port of Antofagasta. This work, after being under consideration for many years, was

saving in distance to America and Japan is striking, as shown in the following computation. The distance to

To	From Buenos Aires Miles	From Antofagasta Miles
New Orleans	6,260	3,419
San Francisco	8,640	4,600
New York	5,838	4,011
Tokio	12,100	9,300

FIG. 1—VIEWS ON NEW TRANSANDINE RAILWAY

A. Heavy rock grading by hand at K. 150. B. The Chani Pass, near line, El. 21,000 ft. C. Mule-team with dynamite for tunnel at K. 180. D. Typical viaduct.

undertaken by the railway administration in March, 1921, work being started in May of the same year. Views on this Transandine section of a new transcontinental line are shown in Fig. 1.

The object of this line is mainly the development of the northwestern provinces of Argentina, which are little known and are practically isolated by the great distance from Atlantic ports. These provinces comprise one of the most promising regions of the world for extensive development, since this region offers a great variety of climate, is watered by numerous rivers and is capable of producing practically everything grown in tropical, sub-tropical and temperate zones. In addition to this, the completion of the line will undoubtedly affect the relations of the United States with Argentina, as a large part of the imports through the ports of Buenos Aires and Rosario de Santa Fé will probably seek this new and shorter route. By sea the

European ports is but slightly increased by the new route, while relations with North America will be greatly facilitated.

Route and Profile.—With a total length of 492 miles from Salta to Antofagasta this meter-gage railway will have 320 miles in Argentina and 172 in Chile, the new construction being about 300 miles and 75 miles respectively. As shown by the map in Fig. 2, the line leaves the existing branch of the State Railways at Rosario de Lerma, 18.6 miles from the city of Salta. Between these points track has been relaid and heavily ballasted to put it in condition for handling the new rolling stock. From the junction, 4,370 ft. above sea level, the line begins its climb on maximum grades of 2.5 per cent, through the gorge of the Toro River, which is followed to Km. 74 (mile 46). The first reaches of this section presented considerable difficulty as the grade of the river bed exceeds 2.8 per cent, the difference

being saved by two switchback sections. Maximum grades are continued, with some easier portions, to the first summit in Abra Munano which is reached in Km. 142 (mile 88) at El. 13,264 ft.

The climb out of the Toro gorge at Puerta de Tastil

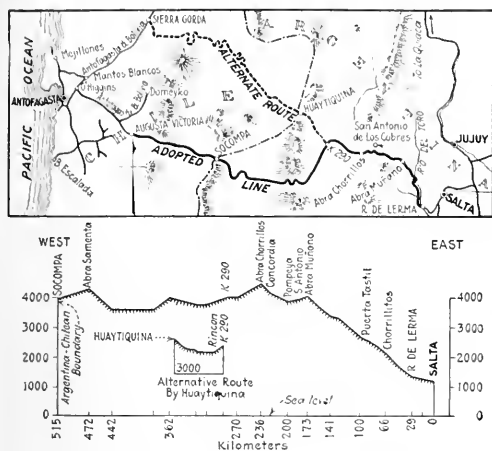

FIG. 2—PLAN AND PROFILE OF ARGENTINE-CHILEAN RAILWAY

is the most interesting feature of this long ascent, recourse having been had to some very heavy development, including two spirals, as shown by Fig. 3. Practically all the difficult part of the construction is comprised in the stretch between Rosario de Lerma and Abra Munano, which is passed with a tunnel about 1,000 ft. long. After traversing some 12½ miles of undulating plain to arrive at San Antonio de los Cobres, capital of the Andes Territory, the line again begins to climb and crosses the Abra de Chorillos, in open cut, at El. 14,681 ft. and a distance of 124 miles from Rosario. Between San Antonio and the Abra de Chorillos the important Concordia mine will be served by a station alongside the pit.

At the Abra de Chorillos the line, after a slight descent, enters on the plateau of the Puna de Atacama which is traversed with only surface work and with very easy grades until the frontier is approached, where 12½ miles of heavy cutting bring it to Socompa on the continental divide, some 310 miles from the start and at El. 12,989 ft. Crossing the plateau, there will be some very long tangents, the longest being 43½ and 25 miles, both completely level. From the frontier the line in Chilean territory will run around the Domeyko range to connect with the terminus of the existing railway of 30-in. gage at Augusta Victoria, an important nitrate deposit, at El. 5,871 and 95½ miles from Antofagasta.

An alternative route, originally proposed, was to cross the frontier at Huaytiquina and connect with the Antofagasta & Bolivia Ry. of 30-in. gage at Sierra Gorda (see Fig. 2). The total distance by this route was 564 miles from Salta to Antofagasta, including 202 miles of new construction in Argentina, from Rosario to Huaytiquina, and 238 miles in Chile, from Sierra Gorda to Huaytiquina. By the adopted route the total distance is only 492 miles from Salta to Antofagasta, with 375 miles of new construction.

Climate—Climatic conditions on the first sixty miles of the new line are extremely unfavorable, the rainfall being very heavy during the summer months (December to March). Floods are frequent in the rivers and have made necessary the construction of massive protection walls and retaining walls to protect the line against bank erosion and landslides which are facilitated by the very loose character of the soil. The rains of this year have been of exceptional nature and have served the very useful purpose of demonstrating that the provisions made for the protection of the line are ample and that little difficulty is to be anticipated on this account.

In the higher reaches of the line, the precipitation is very light and there will be no difficulty from snow, as the only district where snowfall is appreciable is in open claim where drifts do not form. Above El. 9,840 the country is barren, but some vegetation (sage and greasewood) is found as high as El. 15,744 ft. and in sufficient quantity to serve as fuel for the grading gangs. The topography is very broken as far as Km. 200 (mile 124) where the undulating plain of the Puna begins.

Grades and Switchbacks—Grades have been kept down to 2.5 per cent throughout and are compensated for curvature, the compensation on curves of minimum radius, 492 ft. (150 meters) being 0.04, bringing the profile grade down to 2.1 per cent.

Curvature is extremely heavy, averaging 133 deg. per kilometer (200 deg. per mile). Tangents aggregate 52 per cent of the total line.

Switchbacks have been found unavoidable in two cases, but are short (2,624 and 3,938 ft.). Both of these are shown in Fig. 5. The tail tracks are 1,190 ft. long, laid out on easy vertical curves and having the ends covered with sand to check trains that may be run too far. The construction of the tail tracks has required in one case the introduction of a 230-ft. tunnel and in the other a small viaduct. Both switchbacks are located at stations, thus reducing the number of halts to a minimum and permitting the station force to look after the operation of the switches.

Bridges and Viaducts—Many important bridges and viaducts are necessitated by the crossing of numerous lateral valleys (see Fig. 1). Viaducts are of the general American type with steel towers on concrete pedestals, the tower spans being 32.8 ft. long and the

FIG. 4—RIO BLANCO STATION AT ENTRANCE TO TORO GORGE

plate girder spans between towers being generally 65.6 ft. Bridge steel is supplied partly from the United States by the McClintic-Marshall Co. and partly from Germany by the Krupp and the Guttehoffnungshutte concerns. Preference has been given to plate girder

construction with trough flooring and all small culverts have solid reinforced concrete floors. Bridge erection so far has been done by local contracting firms, but it is proposed to build some of the larger viaducts ahead of rail by giving the contracts for the erected structures to responsible and experienced firms.

Tunnels and Slide Protection Works—Tunnels will be twenty in number, varying in length from 230 ft. to 1,542 ft. They will be in all classes of material, from loose sand to very hard granite. Typical sections are given in Fig. 6. Complete drilling and compressor machinery has been supplied by the Ingersoll-Rand Co., but many of the tunnels are being excavated by hand. As a general rule the European contractors prefer the top heading method of tunneling, but some tunnels in harder material are being excavated by the usual American system.

In one case the character of the formation has given rise to a very serious difficulty. After completion of the lining the whole side of the mountain (in very badly shattered clay schist) sloughed off, the line of fault passing close to the springing line of the arch, and causing deformation of the lining (16 in. thick at the crown) due to the eccentric thrust of the slide.

To protect the line against slides it has been found advisable to build some 400 ft. of "cut-and-cover" tunnel (Fig. 6), but it is probable that experience will demonstrate the necessity of greatly increasing this figure. In one case the line crosses under a considerable affluent of the Toro in cut-and-cover, as it was found impossible to construct a bridge over it without loosening the support on the sidehill slope.

In the zone of heavy rainfall many heavy retaining walls have been built to protect the line against slides. All walls are of the gravity type. Toes of banks subject to flood attacks have been protected by defence walls. The Toro is the only river that has required work of this class, which has been limited, as far as possible, by carrying the line well up on the slopes beyond the action of the river. In most places bank protection has been carried out in concrete or rubble masonry, but where the action of the river is not particularly to be feared, "sausages" of stone wrapped in woven wire are used with excellent results.

Masonry defence walls at the toes of embankments are constructed with short spur walls or groins at right angles with the main wall, as shown in Fig. 7. These spurs are about 33 ft. long and 66 ft. c. to c. The author's experience of many years in this region has demonstrated the absolute necessity of providing the spur walls to avoid scour and undermining along the main wall.

Shops and Yards—Large shop plants and engine terminals are not required, in view of the proximity of the State Railway shops at Tafi Viejo. The roundhouse at Salta (which will be the starting point for all trains) will be enlarged and put in condition to handle the heavy locomotive equipment.

Temporary shops for construction purposes at Quijano, six miles from Rosario, are equipped with machine tools, oxy-acetylene and electric welding plants and everything necessary for the repair of the locomotive and motor-truck equipment.

Construction Plant—Two 70-ton Bucyrus steam shovels will be put to work for ballast and bank widening, using the American-built standard 30-ton side-and-

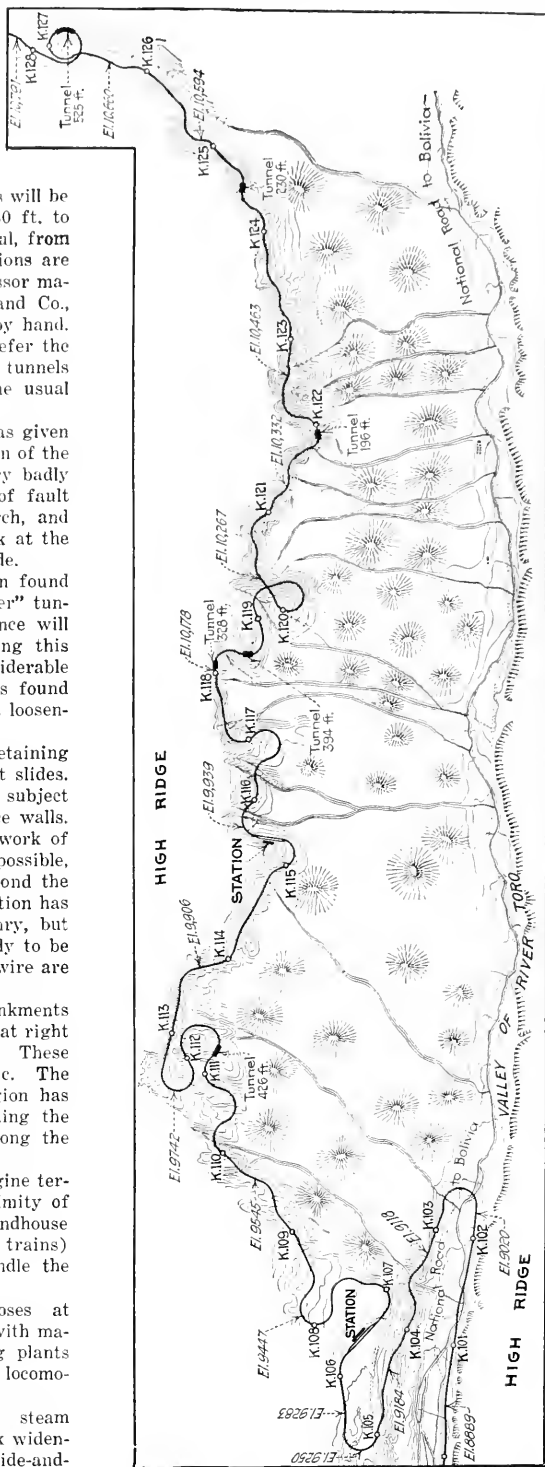

FIG. 8.—DEVELOPMENT IN CLIMBING OUT OF TORO RIVER GORGE. Showing the two spirals and many loops used in gaining height at the expense of distance in this section.

center dump cars built for the State Railways by the Rodgers Ballast Car Co. and the Middletown Car Co. Earthwork has been attacked about 100 miles beyond the rail-head, supplies being carried in by carts and motor trucks. Practically all bridge and culvert masonry has also been completed ahead of rail.

Labor Conditions—All skilled labor is European or Argentine, there being practically no Americans in this part of the world. The peons are mostly natives from the hill country, Bolivians and Chileans, no others can stand the work in the high altitudes. Even with labor accustomed to the conditions, mountain sickness is very common.

Contractors pay by piece work, treating with the

Below: Stone wall 45 ft. high to hold fill across ravine.

head man of each group of workmen. Working hours for men on the Administration force account are eight hours a day and the average daily pay the equivalent of \$2 U. S. gold.

Engineering Staff—For construction the work is divided into sections (five at present), each under a sectional engineer with a full staff of assistants and inspectors. Each section is responsible for the laying out, inspection and payment for all work, as well as for the requisitioning and supply of material to the contractors and company forces.

Six survey parties are in the field, each chief of party reporting directly to the chief engineer. In diffi-

cult country, all surveys are revised by a second party, where possible, to avoid errors of omission in grasping the possibilities of the country.

Progress—The rail-head on Feb. 1 was at Km. 70 (43½ miles from Rosario de Lerma); earthwork was contracted and practically finished up to Km. 140 (mile 47) and was well under way out to Km. 200 (mile 124). No work had been contracted ahead of this point. Advance of the rail-head will be delayed for some months by uncompleted tunnel work, but should reach San Antonio early in 1924. Work from Socompa eastward, on Argentine territory, will be started shortly and it is hoped to have the rails at the frontier by 1926.

Work on the Chilean section has been limited to surveys, but a diplomatic agreement between the two governments will require construction to be started at once. This agreement has yet to be ratified by the Chilean Congress. The work to be done in Chile is comparatively light, consisting of the construction of about 74½ miles of line and reconstructing to meter gage the 95½ miles of 30.4-in. gage from Augusta Victoria to Antofagasta.

Track and Signals—Track on the Argentine section is being constructed in a very substantial manner. Rails are 75 and 80 lb. per yard, laid on red quebracho ties 4.8 x 9.6-in. and 6.56 ft. long, with 2,400 ties per mile. The roadbed is heavily ballasted with broken stone or clean river gravel and has liberal ditching. All stations will be protected by home and distant signals. Train movement will be controlled by the absolute staff system and in addition the Western Electric Co.'s system of train control will be installed at all stations. The operation of trains through the switchbacks will be protected by electric interlocking, while all main-line switches will be equipped with mechanical interlocking, working in conjunction with the signals. In short, the line will be put in condition to handle an intensive traffic efficiently.

Equipment and Traffic—Locomotive equipment includes ten Baldwin engines of the 2:10:2 type, six 4:8:2 and one 2:8:2. Those of the first two types are oil burners and are the most powerful locomotives in use in the Argentine Republic. The equipment includes sixteen motor trucks of 4- and 7-ton capacity and eighty cars of different types, but mostly flat cars. This equipment is supplemented with some 160 six-mule carts and a large number of pack animals.

This railway project is the most ambitious that has been undertaken in South America, limiting conditions of grade such as are here employed never having been attempted in crossing the main chain of the Andes. But the additional cost due to the low grades will be amply justified by the reduction in cost of operating. Freight traffic in sight, discounting increase due to opening up a rich country, is estimated at 478,000 metric tons annually, of which 220,000 tons is eastbound and 230,000 tons westbound and 28,000 tons local business. Passenger traffic will require a daily train in each direction. As the capacity of the 2:10:2 locomotives is 460 tons on the maximum grades, the line will have to provide at once a service of four or five daily trains in each direction.

Great credit must be given to the Argentine Government authorities and the officers of the Argentine State Railways for the courage with which they confronted this great work and for the way in which they have kept the working forces in the field supplied with materials and money in face of much opposition.

Notes on the French Industrial Situation

By Our Paris Correspondent

THERE IS but one compelling influence which dominates French economic, industrial and financial spheres today: the necessity for stabilization.

The most urgent reconstructions in France have been undertaken and for the most part carried to completion in the devastated regions where, on June 30 last, 7,875,000 acres out of 8,250,000 acres had been reclaimed and restored to cultivation, 20,000 factories out of 22,900 rebuilt and "reorganized," and 590,000 dwellings rebuilt out of 741,993 destroyed. The population of the invaded districts is today but 400,000 below that of pre-war figures and is already paying taxes to the government of 3 billion francs a year, whereas in 1920 the figure was but 600,000,000 francs.

Building costs are the obvious deterrent from a more intensive construction campaign of the moment, less so with respect to materials than to labor. In spite of this the very necessary reconstruction of the devastated regions, as well as the delayed public works which were left stagnant during the war period, have made a demand for most lines of raw and semi-fabricated materials such as was never before known.

Cement Demands—In so far as this has affected the portland cement industry recent reports of four leading French manufacturing companies are pertinent as to facts and figures showing the present value of such industrial property. Before the war a metric ton of portland cement sold in France for 30 to 35 francs; soon after the armistice it was quoted at 280 francs and today at an average figure of 115 francs, rising to 125 francs in some districts. The before-the-war price was nominally \$7 per ton at the then ruling rate of exchange; that of today (with a six-cent franc) about the same in case the product was bought with American cash by some American firm operating in France, but at a figure which is three and a half times that if the purchaser is a Frenchman buying with francs. This comparison shows the anomalous state of affairs which the American often ignores in quick estimates of the situation in France today.

A. Antoine, of the Bureau des Ponts et Chaussées, upon return from a recent visit to the United States made a report to the Comité Michelin d'Organisation Rationnelle and the Syndicate of Public Works Contractors, presided over by Monsieur Michelin, the automobile tire manufacturer, on his observations of the comprehensive and elaborate road building being carried out in America.

The mere mention by M. Antoine of 79,000,000 sq. yd. of concrete roadway having been laid in the United States in 1922—7,480 miles of an 18-ft. roadway, or the equivalent of almost the entire length of the Routes Nationales of the first class in France, was received with appalling silence. The next step was to find the ways and means by which this progress might be equaled in France. There was the difficulty. Taxation in all its forms on automobile road users in particular, has reached the limit of tolerance. Above all he argued for the use of concrete as being the material which gave the best results in meeting an intensive light and heavy

automobile traffic such as is at present being imposed upon the *macadam* and *tresaguet* French highways, which they were never intended to stand up under. His statement that such a road surface would, if properly laid as in America, last twenty years with a low maintenance cost was especially well received by the French authorities who well recognize the necessity of adopting some rapid and efficient measure which shall lift French roads out of the slough into which they were fast falling. It is claimed that all the raw material required for such roads can be found within the French frontiers. It is doubtful if the same can be said of the new machinery which will be required. For many kinds of modern machinery adapted to uses which were formerly carried out by manual labor, France is still dependent upon the outside world.

Housing Progress—Various organizations in France, without any specific government encouragement, are occupying themselves with low-priced dwellings for an ever increasing suburban population as distinct from town dwellers or the purely rural population. Italy, on the contrary, through a government department is actually offering financial aid to private enterprise in this direction. Belgium has a government-controlled standardization bureau where building materials of various kinds are offered at a "standardized" price.

In France private initiative alone has been able to show a homeless and home-desiring public—first by necessity in the devastated regions and later in suburban Paris, Bordeaux, Lyons and Marseilles—how to build a modest dwelling in a third of the time ordinarily required and at half or two-thirds the cost of construction by old methods. The following prices are quoted for the construction of small dwellings for workingmen in the Paris district:

	Two-Room	Three-Room	Four-Room
	(Prices in Francs at \$0.06)		
Wood chalet	6,000	9,975
Steel construction	5,940	8,235
Wood and plaster	6,400	9,770	12,500
Agglomerated slag brick	7,950	11,150	17,000
Compressed cement blocks and binder (System Charpentier—Etablissements Charpentier, 188 Boulevard St. Germain, Paris)	5,900	8,500	11,400

Some fifty-odd structures after the last mentioned method (compressed concrete blocks with a cement binder forced into the joints under pressure) have been erected by this firm, which abandoned a long traditional career to espouse this new idea of fabricating the modest cottage home at a lower figure and in a more solid manner than was known before. The figures translated into dollars, \$360, \$510 and \$684, respectively, are certainly cheap. The owner's handkerchief-plot of land may well be had for the equivalent of another \$150 within ten miles of the Paris fortifications. Here, perhaps, is the solution of a big economic problem.

Not wholly unrelated to the above project is that of the city of Paris which proposes, by competition, to erect a series of workers' tenement buildings. The plan is for the moment checked by reason of the attitude taken by the Society of Federated Architects. When it was learned that the project was to be carried out by four *salaried* architects whose designs should be accepted, a protest was made to the effect that such an arrangement would be the "reduction of a high class profession to that of a mere city employe without position or dignity or proportional honoraria." There the matter stands. The French are like that—sometimes.

Metal Production—Aside from the wholly enviable situation of France as a self-producing country in most things of the table its prime position in metallurgical affairs is what gives, or will give, it a predominant influence in European metal markets. Indeed, the part that France is likely to play in the export metal market, even to structural steel shapes and almost everything except wire, plates and sheets, can hardly be estimated as yet in view of the liquidity of the situation. Certain well-informed French "journals of opinion"—not what we know as newspapers, be it remarked, but printed sheets which are all potent in France—are daily urging an association of Ruhr and Lorraine metallurgical interests 'o control the combined output of the two contiguous regions, a plan which, if followed, will combine to make the most formidable iron and steel and allied industry—trust, consortium, call it what you will—in the world. The proposition is not without a logical backing. The ways and means have yet to be provided but there is an undoubted disposition on the part of many French and German elements tending toward this as a possible solution of a problem which is daily becoming more and more obscured by outside issues.

As to the possibility of France becoming a world factor in metallurgical affairs the following figures eloquently point the way:

FRENCH EXPORTS, FIRST SIX MONTHS, 1923

	Frances
Pig iron	128,897,000
Ferro-alloys	10,221,000
Semi-finished and finished iron and steel products.....	1,555,378,000

FRENCH EXPORTS TO UNITED STATES DURING ONE MONTH OF 1923

	Frances
Pig iron	3,850,000
Iron and steel products	1,410,000
Machinery and parts	1,378,000
Tools and manufactures of metal.....	1,424,000

Employment—That the French workingman, whatever be his trade, is well occupied is shown by the figures of the French Foreign Labor Bureau for the week of July 30 to August 4. There were actually placed 5,677 foreigners, including 2,307 Poles, 1,925 Italians, 511 Belgians, 239 Spaniards, etc. Of this number the iron mines took 85, coal mines 239, navvys accounted for 439, building trades 956, laborers 1,115, agricultural laborers 1,655, etc.

The trades union authorities in France have recently opened a "consultation" as to the actual operation of "workers' councils," or shop committees, where they have been introduced. This movement shows with what precision of detail the communists, the French political party, with representatives in parliament, with which the movement is associated, are studying the ways and means of replacing the power of the employer and capitalist at some future day with some species of sovietic regime and organization. It seems almost futile that they should hold out for any such solution in France, for the country and its people are by intent, preference and tradition wholly against interference with individual rights, among workers as among others.

Transportation—One of the biggest canalization jobs ever undertaken in western Europe is about to come into being in making the River Rhone navigable between France and Switzerland—Lyons in mid-France to Geneva at the western end of Lake Lemman. France, in order to be sure of a sufficient water supply at all

times, insists that Switzerland shall first raise the level of Lake Lemman. Switzerland claims that this would prove a real inconvenience to river property owners and dwellers on the shores. At the last meeting of the International Rhone Conference the Swiss delegates demanded that Swiss barges and canal boats should be free of French taxes on their voyage from Geneva to the Mediterranean, the proposition being rejected or ignored by the French delegates. The reply of Switzerland was to protest that the level of Lake Lemman could not be raised.

A big lock is to be built at Genissat between the Swiss frontier and Lyons and a great distributing port just outside of Lyons down-river. The entire work is merely under discussion and economic and political interests are at work to block it in favor of a direct railway from Switzerland due west to the twin ports of Nantes and Saint Nazaire, where there remain the embryonic port facilities which were elaborated by the American army in France and which can care for a far more considerable traffic than France alone can feed to them. One or the other or both these projects are bound sooner or later to come into being but financial matters and international common accord are yet to be reconciled.

The channel tunnel between Calais and Dover has come again on the tapis these last days but the French interests have manifestly not the available capital to put into it and British interests are still discussing the possibility of a tunnel being a danger to Great Britain in case of war. Real or fancied boogies like these are what are holding back the progressives in France.

The already decided electrification scheme for French railways is one aspect which has not suffered from a like lethargy and both the Midi and the Orleans railways have already begun the erection of hydro-electric plants which in from five to ten years will give electric power for the running of trains over the greater part of the minor lines of their respective systems.

Lighthouse Power Increases in 2,600 Years

In describing the new 3010 candlepower harbor light for Port Said, *Engineering*, a British publication, states that: "To Egypt belongs the credit of the erection of the first lighthouse on record, namely, the tower built on the island of Pharos at the mouth of Alexandria Harbor, about 660 years before the Christian era. This tower was 100 feet high and stood as a monument to an ancient civilization until the fourteenth century when it was washed away by the sea. Its light consisted of an open fire of burning wood, and the same practice was followed in all subsequent lighthouses until the beginning of the seventeenth century. Even as late as 1790 the South Foreland lighthouse was merely a beacon fire of coal. The famous Eddystone Lighthouse, in 1759, was lighted by 10 lb. of tallow candles, a clock being provided to ring a bell every half-hour to remind the keeper to snuff them. In 1763 oil lamps with reflectors were used for the lighting of the Mersey Channel, and after the invention of the Argand burner twenty years later oil became the standard illuminant. Mineral oil was introduced in 1872, and the concentric wicks of the Argand burner in due course gave way to the incandescent mantle, which now furnishes light for all the most important lighthouses of the world."

Trapezoidal Portal and Eccentric Heel-Joint of Truss

BY CAMILLO WEISS

Bridge and Fabrication Department, Bethlehem Steel Co., Bethlehem, Pa.

ANALYSIS of statically indeterminate structures is usually laborious and time-consuming unless formulas are available. On the other hand the value of ready-made formulas depends on the exactness of premises and the reliability of typography, both of which should be checked by the discriminating user. A formula well understood is usually of great advantage as to speed and accuracy in practical application. Formulas are therefore given in the present article for a frequently occurring case, namely the trapezoidal portal carrying an unsymmetrical load. This type of structure is encountered more frequently than will be recognized at first sight. It is of common occurrence in the eccentric heel-joints of roof trusses.

Looking back only eight years, the heel-joint problem received considerable space and attention in the technical press, and brought forth some astonishing solutions. Finally, a graphical method was offered by Prof. E. H. Rockwell, in *Engineering News* of Oct. 21, 1915, which implied certain assumptions similar to those underlying this analysis, and which is in good agreement with the analytical method presented in the following discussion.

The relations given below were derived by the slope-deflection method which is described in detail in "Analysis of Statically Indeterminate Structures by the Slope Deflection Method," by W. M. Wilson, F. E. Richart and Camillo Weiss, Bulletin 108, Engineering Experiment Station, University of Illinois.

Trapezoidal Portal—For the portal in Fig. 1, hinged at C and T and carrying a load of R lb., the following relations may be established when deformations due to shear and to direct stresses are neglected:

Bending moment at A, in in.-lb.,

$$M_A = R l_1 \left(1 - \frac{l_1}{p} \right) \frac{\frac{l_1}{I_1} + \frac{3l_1}{2I_2}}{\frac{l_1}{I_1} + \frac{l_2}{I_2} + \frac{3l_1}{I_3}}$$

Bending moment at B, in in.-lb.,

$$M_B = R l_1 \left(1 - \frac{l_1}{p} \right) \frac{\frac{l_2}{I_2} + \frac{2l_1}{I_3}}{\frac{l_1}{I_1} + \frac{l_2}{I_2} + \frac{3l_1}{I_3}}$$

Reactions and direct stresses, in lb.,

$$\begin{aligned} C &= R \frac{l_1}{b}; & T &= R \frac{l_1}{a} \\ H_1 &= \frac{M_A}{l_1}; & H_2 &= R \left(1 - \frac{l_1}{p} \right) - H_1 \end{aligned}$$

In these formulas I_1 , I_2 and I_3 are the moments of inertia of the respective members, and l_1 , l_2 and l_3 , a , b , and p are lengths, in inches, as indicated. It will be noted that the sum of the two moments is

$$M_A + M_B = R l_1 \left(1 - \frac{l_1}{p} \right)$$

This equation, which may be obtained directly from the static conditions of equilibrium, shows that the sum of the two moments is independent of the shape and area of cross-sections. It approaches zero as l_1 approaches p , and equals the quantity $R l_1$ if p becomes

infinity, and the portal rectangular. This is exactly as should be expected.

Eccentric Heel Joint—The above derivations are immediately applicable to the eccentric heel joint of a roof truss, shown in Fig. 2. The direct stress in the

top chord is $C = R \frac{l_1}{b}$, and the direct stress in the

bottom chord $T = R \frac{l_1}{a}$. The quantity $\frac{l_3}{I}$ is relatively so small that it may be neglected for all practical purposes, simplifying the equations to

$$M_A = R l_1 \left(1 - \frac{l_1}{p} \right) \frac{\frac{l_1}{I_1}}{\frac{l_1}{I_1} + \frac{l_2}{I_2}}$$

and

$$M_B = R l_1 \left(1 - \frac{l_1}{p} \right) \frac{\frac{l_2}{I_2}}{\frac{l_1}{I_1} + \frac{l_2}{I_2}}$$

For flat roofs the difference between l_1 and l_2 may also be neglected, furnishing the very simple formulas

$$\begin{aligned} M_A &= R l_1 \left(1 - \frac{l_1}{p} \right) \frac{I_3}{I_1 + I_2} \\ M_B &= R l_1 \left(1 - \frac{l_1}{p} \right) \frac{I_2}{I_1 + I_2} \end{aligned}$$

In all cases the moments at F and G are found by the expressions $M_F = H_2 l$ and $M_G = I_4 l$.

DIAGRAMS FOR MOMENT FORMULAS

Nothing has been said so far to fix the location of the points of contraflexure, except that their relative position is implied to be in a vertical plane. The actual location of points C and T will depend on the relative degree of restraint at points A, B, F and G. If points F and G were pin-connected, which assumption underlies all truss analyses for primary stresses, l would be zero, point C would coincide with point F, and point T with point G. If the restraints at A, B, F and G are of equal degree the points of contraflexure are at the centers of the members AG and BF respectively. Special conditions in any given case will influence the location of the points of contraflexure and require the judgment of the engineer.

Assuming contraflexure at the mid-points, the bending moments at A, B, F and G will be greatest when the end panel is about six-tenths of the full panel length, i.e., if $l + l_1 = 0.6(l + p)$. The influence line for these moments, as the heel A moves from O toward G, is part of a hyperbola, the axes of which are inclined toward the line OG.

Rapid Construction of Earth-Fill Dam in California

Half Million Yards of Embankment Constructed in Six Months Using Hydraulic Fill Between Dry-Fill Slope Embankments

BY CHARLES H. RICHARDS

Associate, Engineering Office, J. B. Lippincott, Los Angeles, Calif.

HENSHAW Dam on the San Luis Rey River, San Diego County, California, was designed and built in eight months and is now impounding water. It is believed that this time establishes a record when the size of the dam and its remoteness from facilities are considered. The nearest railroad point is 40 miles distant and the nearest supply point, San Diego, is 65 miles away. The dam is also at an elevation of 2,700 ft. above sea level and the roads leading to it are generally mountain grades.

The dam was built for the San Diego County Water Co. to impound water for domestic and irrigation supply, the latter being the larger demand. Power will also be developed at various points along the course of delivery. It will impound the runoff from 210 square miles of mountain watershed, with elevations of 2,600 to 5,000 ft. above sea level, and will create a reservoir of 203,000 acre-feet capacity, which will afford a net safe yield of 28,000 acre-feet annually. A characteristic of the San Luis Rey River is its periodic high flood discharge which has been measured as 28,000 cu.ft. per second. It was the possibility of having such a flood condition that necessitated the building of the dam between two rainy seasons.

In the locality of the dam the rock is more or less fractured and did not assure stable foundations for a concrete structure, but core drill exploration of two sites indicated that an earth-fill dam was adaptable. Again a large spillway is necessary to pass the waste flood waters and since the material in the wasteway was suitable for the outer portions of an earth dam, with a hydraulic-fill center, this type was decided upon. The excavation from the spillway was decomposed granite, with relatively small quantities of fines, and therefore it would have been difficult to construct an impervious dam using this material alone. In order to store the coming winter's runoff it was necessary that all possible speed be made in raising the dam. The site was so narrow that it would have been impossible to complete the dam within the required time by the dry-fill process alone, due to team congestion.

As shown by Fig. 1 the main dam is 117 ft. high from the river bed and the core trench was excavated to a depth of 33 ft. below the stream, giving a total height of 150 ft. Owing to the fractured nature of portions of the cutoff trench, holes 2 in. in diameter and about 20 ft. deep were drilled in the bottom. There were two lines of holes, 6 ft. apart and on 6-ft. centers, staggered. Grout under 100 lb. pressure was forced into the rock through these holes.

The slopes on the two faces of the dam are symmetrical, $2\frac{1}{2}$ on 1 for the first 50 ft. and $2\frac{1}{2}$ on 1 for the remaining height. These slopes required a bottom width of 600 ft. and the top width was fixed at 20 ft. The main dam is 650 ft. long and contains 400,000 cu.yd. exclusive of the bottom trench. There were 10,000 cu.yd. in this trench, excavated and placed in the outer toes of

the fill. A core trench varying from 13 ft. to 5 ft. in depth and from 8 to 5 ft. in width was carried up the slopes of the abutments connecting at its lower end with the bottom trench. All loose and trashy material was stripped from the abutments.

Two smaller dams adjacent to the main dam, Fig. 1, containing about 50,000 cu.yd. were also constructed during the period of building the main dam. These dams are dry earth fills, sprinkled and tamped with petrolithic rollers.

As indicated by Fig. 1, the upstream faces of all the dams are paved with 4 in. of 1:3:6 concrete, reinforced by 6x6-in. wire mesh of welded steel. The concrete was poured in 15-ft. panels, alternate joints being made expansive. The lower 45 ft. of the main dam is riprapped with large boulders to a depth of 3 ft. These boulders were wasted from the dry fill as they delayed the progress of the wagons delivering material. Also the downstream toe of the main dam has a riprap apron 10 ft. deep extending 20 ft. in elevation above the toe. In addition to this apron there is a mattress of large boulders covering the original stream bed to a depth of 10 ft. and extending down stream from the toe 100 ft. for the full width of the canyon. This mattress was placed to protect the toe from the back wash of the spillway discharge. The rocks used average about 20 cu.ft. and were placed by a stiff-leg derrick with a 75-ft. boom.

Accessory Structures—The spillway is practically a continuation of the main dam. It is 10 ft. lower than the dam and has a crest length of 500 ft. After leaving the lip the water will flow down a 1 on 1 slope varying from 5 to 15 ft. deep vertically, into a channel paralleling the lip. This channel is 35 ft. wide at its upper end and 180 ft. at the lower end. From it the water will drop to the stream bed on a $1\frac{1}{2}$ on 1 slope, discharging into the stream after passing over a hydraulic jump designed to reduce the cutting velocity. The wasteway is lined with concrete 6 to 9 in. thick, reinforced with $\frac{3}{4}$ -in. corrugated bars on 12-in. centers in both directions. The steel is placed near the top for expansion and contraction stresses. Expansion joints filled with asphaltum are spaced 30 ft. both ways. Cutoff walls of plain concrete are spaced about 100 ft. apart and extend into the rock 2 ft. below the bottom of the concrete. At the point where the stream leaves the concreted section a cutoff wall 5 ft. thick and 15 ft. deep has been constructed. All concrete is 1:3:6.

When the dam was begun it was thought that possibly sufficient height could not be attained before the early rains set in. To provide for this contingency a flood culvert, as shown by Fig. 1, of horseshoe shape, was designed. Crushed rock was not available at that time so a concrete of 1 cement to 2 sand, heavily reinforced, was used. Gates are not provided, but two recesses, one at the upstream entrance and one at the center of the dam, were left for plugging when the dam was high enough to store possible floods. From these plug recesses 6-in. pipes were carried through the dam to the top to be used later in pouring the concrete in the plugs. The pipe to the central plug was embedded in 3 ft. of concrete which was the thickness of the culvert shell at this point. Notwithstanding this support, the weight of the pipe and the settling of the clay hydraulic fill pulled the pipe 9 in. down through the concrete. A flange on the pipe above the concrete would probably have prevented this.

An outlet tunnel of the section shown by Fig. 1, was bored through the south abutment, lined with concrete and grouted under 100 lb. pressure. On the axis of the main dam a two-compartment shaft 100 ft. deep connects with the tunnel. At the bottom of the compartment nearest the reservoir an emergency wooden gate and a cast-iron gate, both 4 ft. square, are installed. A 36-in. gate connects the two compartments 35 ft. from the bottom. A similar gate 70 ft. from the bottom has also been installed. The four gates are operated from a gate house on top of the dam.

Construction Equipment—Four steam shovels with $\frac{1}{2}$ -cu.yd. buckets were used in the excavation, each work-

ing a 3-in. tail rope leading to blocks on a cable strung across the top of the steep slope, while a 3-in. cable was used to drag the scraper with its load.

The hydrauliclicking equipment was in duplicate, each unit consisting of one 10-in. two-stage, centrifugal pump and two 12 x 30-in. single-stage centrifugal rock pumps. The 10-in. pump delivered 7 sec.-ft. at 140 lb. pressure at the nozzle, which was 1,000 ft. away at its maximum distance, and was driven by a 400-hp. motor.

The pipe used was 10 in. in diameter, of flanged, riveted steel. This pipe carried the water to 3-in. giant nozzles, used to break and wash down the clay banks. From these faces the material flowed through ground

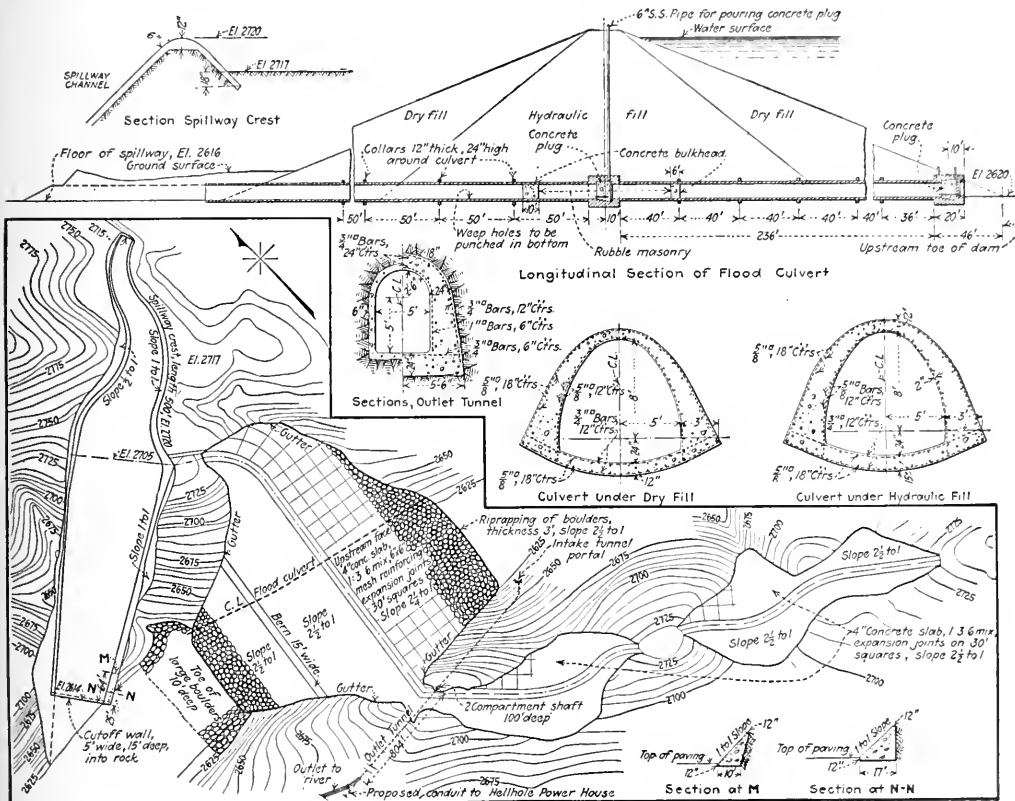

FIG. 1—PLAN, SECTION AND STRUCTURES OF THE HENSHAW DAM

ing two nine-hour shifts for six days a week. The material in the dry fill was hauled from the shovels in $\frac{1}{2}$ -cu.yd. dump wagons drawn by two mules. When the grade became too steep, snatch teams, tractors and electric hoists were utilized to assist the single team. When tractors were used, two wagons were coupled into a train. A maximum of 2,800 cu.yd. was obtained in one day of two shifts, or an average of 466 cu.yd. per shovel per nine-hour shift for each of the three shovels. The maximum for one shovel for one nine-hour shift was 809 cu.yd. A large fresno, with shovel teeth, was built to pull the material from the $\frac{1}{2}$ on 1 slopes in the spillway to a point where the shovels could pick it up. This was operated by a 50-hp. double-drum motor, having a

sluice ditches on a 3 per cent grade to the 12-in. rock pumps. These pumps required 10 sec.-ft. of water, therefore an auxiliary supply of 3 sec.-ft. was delivered to them. The average of solids transported was 9.6 per cent. From these pumps the material was transported to the dam 2,000 ft. away, through 12-in. diameter welded slip-joint pipe, the steel composing it being known as hard red metal. Two hundred horsepower variable-speed motors were direct-connected to the rock pumps. The pumps were lined with white iron, the liners lasting for about 50,000 cu.yd. before renewal was required. Power under 22,000 v. was brought in through a line 18 miles long. A synchronous condenser of 350 amp. was installed at the dam to improve the load factor, etc.

FIG. 2—UPSTREAM SEAL OF FINE CLAY DISCARDED FROM HYDRAULIC FILL

To insure a continuous supply of power, a standby electric plant was installed at the dam. This consisted of two 200-hp. semi-Diesel engines, each direct-connected to a 176-kw. alternator.

Portable compressors were used for furnishing air to the drills. Small drills and a large churn drill boring 6-in. holes were used in the excavation of the spillway.

This analysis shows a relatively large fine clay content. With the fast schedule of construction it was deemed desirable to waste some of these fines as several notable examples of failure of hydraulic-fill dams indicated the danger of rapidly building a dam of this type with a large per cent of very fine material. The fines were allowed to flow off with the excess of water and were deposited above the upper toe of the dam, making an effective seal on the sand at this point. This condition is shown in Fig. 2.

A mechanical analysis of a sample of the clay core material after deposition was as follows:

2-1 mm. (F. G.)	1.560
1-5 mm.	1.560
.5-.25 mm.	1.600
.25-.10 mm.	18.040
.10-.05 mm.	58.662
.05-.005 mm.	12.943
.005 mm.	5.846

100.216

The sandy portions of the fill had 26.4 per cent voids and weighed 111 lb. per cubic foot in place, while the clay portion weighed 120 lb. per cubic foot when dried to the consistency of putty.

When the dry-fill toes had reached the point where they were too narrow to work teams, dry-fill material

FIG. 3—CROSS-SECTION SHOWING DEPOSITION OF EMBANKMENT MATERIALS

Method of Placing Fills—The dry fill was placed by wagons, spread with small mormon scrapers, and kept wet by sprinkling. Tamping was accomplished by the continual stream of wagons and mules; 1 cu.yd. of loose material compacted to 0.8 cu.yd. in the dam and weighed 3,510 lb. per cubic yard in place. A large percentage of rock was incorporated in the dry fill, particularly on the down-stream toe. An excess of rock made the going too severe for the wagons; when this condition arose the larger rocks were placed on the faces of the dam to form riprap protection. There has been 13 in. of rain on the slopes unprotected by riprap and due to the rocky nature of the face, washing has not taken place. The dry fill was carried approximately 10 ft. above the water level of the summit pool used in the separation of materials in the hydraulic fill.

The hydraulic fill material in the borrow pits was approximately 66 per cent sand and gravel and 33 per cent clay, and analyzed as follows:

Per cent passing 200 mesh	22.30
Per cent passing 100 mesh	39.50
Per cent passing 80 mesh	52.50
Per cent passing 50 mesh	66.00
Per cent passing 40 mesh	72.80
Per cent passing 30 mesh	80.00
Per cent passing 20 mesh	89.60
Per cent passing 10 mesh	98.15
Material washed out, per cent.	29.75
Per cent material passing after washing	34.25
Total fines washed out and passing 100 mesh, per cent.	55.00

Abrams test for humus indicated a small quantity of organic matter.

was dumped upon the sand beaches of the hydraulic fill. These could then be driven on in two or three hours after placing. This method gave an inverted saw-tooth profile, Fig. 3, to the line between the sand beaches and the dry fill. The progress of the various units of the work governed this line to a large degree. A delay to either of the fills usually meant an encroachment beyond the theoretical line between the fills. These theoretical lines were established by survey and were followed generally, being deviated from only when necessary to avoid stoppage of work.

The hydraulic-fill material was brought through pipes and deposited in about 5 ft. of water, Figs. 4 and 5. A maximum of 3,000 cu.yd. in 24 hours was sluiced out of the borrow pits and when placed in the dam increased in volume by 16 per cent due to the separation of the clay from the voids in the sands. An average of 65,000 cu.yd. per month was obtained, while putting in the bottom portion of the dam. A 16-in. overflow pipe made up of double well casing in 24-in. lengths carried the surplus water back to the reservoir where it was again used for transporting clay to the dam. A collapse of an angle in this pipe was the only defect in the hydraulic equipment.

Test Results—Continuous tests were made of the consolidation if the clay core, using a 6-in. cast-iron ball as the measure of penetration with the following results:

Date	Elevation of Water Surface	Depth to Clay	Penetration in Clay
Sept. 15	2632	1.0	5.4
Oct. 1	2645	3.0	5.4
Oct. 8	2663	5.0	6.2
Oct. 17	2675	7.0	5.1
Oct. 19	2675	5.0	2.7(1)
Oct. 23	2682	9.0	3.0(2)
Oct. 30	2688	4.0	3.0(3)
Nov. 10	2692	3.0	3.5(4)
Nov. 17	2702	6.1	3.3(1)
Nov. 27	2713	3.0	2.0(1)

(1)Average of three; (2)Average of five; (3)Average of two; (4)Average of four.

In addition to these tests, holes were drilled through the culvert into the clay and fitted with 2-in. pipes with valves. Pressure gages were connected at various times and the pressures recorded. On Oct. 19 when the static head on the clay and gravels was 50 ft., the water pressure recorded in the gravels was 8 lb. per square inch and the pressure in the clay was 5 lb. per square inch. When this pressure obtained, the 2-in. pipe would exude the clay material at the rate of 0.13 cu ft. in one hour. With the clay in this condition a 1½-in. pipe could be worked into it by one man for a distance of 7 ft. On January 31, 1923, no pressure showed in the clay. No exudation took place in twelve hours and a ¾-in. bar sharpened at one end could be pushed into the clay for a distance of 5½ ft. showing a very high degree of consolidation.

Tests were made to determine the settlement of the dam. Blocks of concrete were set on each face (Fig. 1) at points one-third and two-thirds of the vertical height above the river bed. Two per cent was added to allow for shrinkage. The following table indicates both the vertical and horizontal movements of the mass.

Upstream Blocks, One-third Way Up; Average of Two.		
Date	Vertical Movement	Horizontal Movement

The dam and reservoir are the fulfilment of the dreams of many people and the project has been under consideration for some thirty years. The realization

FIG. 5—PLACING LAST LIFT OF CLAY CORE

has been possible only through the foresight and financial courage of Wm. G. Henshaw of San Francisco, Calif., President of the San Diego County Water Co., and John Treanor of Los Angeles, manager of Mr. Henshaw's business affairs in Southern California.

Henshaw Dam was built on a cost-plus-a-fixed-fee contract, with bonus and penalty clauses. Bent Brothers of Los Angeles, Calif., were the contractors, their superintendent M. H. Slocum being in charge. The late R. C. Starr, of Thebo, Starr & Anderton, San Francisco, Calif., acted as consulting engineer. J. B. Lippincott, of Los Angeles, is the chief engineer for the San Diego County Water Co. and the writer was construction engineer in charge of the work at the dam.

Cut Building Cost and Increase Floor Space by Study of Plans

A REDUCTION of \$250,000 in cost and an increase of income in the Straus office building now under construction in Chicago, has been effected by submitting the plans to the National Association of Building Owners and Managers for criticism and suggestions as to interior arrangement and equipment.

According to a statement by the owners, the lateral corridor space between the two banks of elevators from the first to the 13th floors, where express cars will not stop, is to be utilized for extra office space. From the 16th to the 21st floors the elevator corridor space in front of the local elevators will be used for office space not previously planned. This arrangement, together with the gain made by making the walls of the interior court perpendicular instead of terraced, is said to give additional rental area equivalent to adding about \$24,000 to the annual income from the building. Further, the elimination of a set-back in the central court at a cost of \$50,000 gave additional rentable space equivalent to \$25,000 annually.

Chair rails on office walls were eliminated, as it was considered that they do not protect the walls, and with thousands of feet of rail at 35c. per foot the saving was appreciable. Other savings were effected by eliminating sidewalk lights, locks on inside office doors, exterior windows in elevator banks, and one stack of toilets throughout the building.

The Straus building, now under construction, will be 32 stories high and its estimated cost is \$15,000,000. Graham, Anderson, Probst & White are the architects for S. W. Straus & Co.

State Engineering In the Highway Bridge Field

Being a Discussion of How Seriously the Field of Private Practice Is Affected By State Highway Bridge Design, By Searcy B. Slack, Atlanta, Ga., and M. W. Torkelson, Madison, Wis.

Charges made against state highway departments by bridge companies and engineers in private practice assert that bridges designed by the state are wasteful, that the engineers employed by the state are incompetent and lack experience, and that the public money would be spent to much better advantage if private engineers were employed to design the bridges. In contrast to present methods, the virtues of the old-time bridge-builder and the methods of a quarter-century ago were extolled by a correspondent in Engineering News-Record of Sept. 28 last, p. 533. The editors have been urged by other correspondents to denounce the paternalistic system of state bridge engineering and advocate a return to freely competitive practice in the interests of the public as well as of consulting and contracting engineers. A committee of the American Association of Engineers has just taken

up the study of how seriously state highway bridge design injures the field of private engineers. In Maine a public statement by the governor recently declared that less costly bridge construction would be adopted; a complete reply to this statement was given by L. N. Edwards, the state's bridge engineer, in the issue of April 19, p. 720. In order to develop the facts of the whole situation, Engineering News-Record asked a number of state highway engineers for facts and views. Below are given two of the replies to this inquiry. Without a single reference to the notorious "bridge letting" conditions of an earlier generation they nevertheless picture very clearly certain evils of former practices, now largely eliminated by the effect of state control. At the same time the two articles suggest certain professional problems of the present day.

—EDITOR.

Former and Present Problems in the Southeast

BY SEARCY B. SLACK

Bridge Engineer, Georgia Highway Department, Atlanta

UNTIL the comparatively recent organization of the state highway departments, except on the large projects and work in a few progressive counties, highway bridge engineering in the Southeast was conspicuous by its absence. The road and bridge work was handled entirely by the county officials, who were generally inexperienced, and exploitation of the field by unscrupulous salesmen and so-called bridge men was the natural result. Honest companies found it difficult to sell good bridges in the face of such competition, and practically all companies were forced to furnish "free engineering." As a result the people, as well as the county officials, did not know what constituted good bridge work and there was little demand for highway bridge engineers.

Realizing the serious side of this situation, in 1912 the engineering department of the University of Georgia organized a good-roads department. The primary object of this department was to help the counties with the road and bridge work and incidentally, by education, to create a demand for highway and bridge engineering. A similar movement was later started in several of the neighboring states. Funds available for this educational work were limited, however, and while good work was being done, it was making slow progress.

With the passage of the Federal Aid road act in 1916, requiring the organization of a state highway department before a state could participate in federal aid, highway engineering took a new lease on life. Highway departments were organized, and work on a better basis was started on the highways and highway bridges. Since this time the education of the county officials and the public in highway and bridge work has advanced rapidly, and there is now some demand for highway bridge engineering. Naturally the counties are turning to the agencies most responsible for the advance of their education and are calling upon the

state highway departments for services which possibly could be more properly rendered by county engineers or practicing engineers. Before the organized highway movement, however, both highway and bridge engineers had, in a large measure, failed in selling their services.

Now that the "good roads" movement has gained great headway and there is some demand for highway bridge engineering, it is a proper time for a discussion within the profession concerning the extent to which it is wise to centralize highway bridge work in state and federal departments. There is undoubtedly a field for both the state highway bridge engineers and the specialized bridge expert. The extent of the fields will vary widely with individual cases. The state departments must needs handle a wide variety of structures, the great majority of which a practicing engineer could not economically handle. In exceptional cases, however, such as deep foundations, spans of unusual lengths or unusual movable bridges, expert advice and direction is generally needed.

Many thoughtful people are beginning to catch a glimpse in retrospect of the exploitation and abuses which have been going on at the hands of both bridge companies and engineers, and as a result demand some kind of general supervision by a recognized state agency. Matters of concern to the engineering profession are the abuses within the profession which are so largely responsible for shaking public confidence in engineers. These abuses are quite general, but a few specific examples of more glaring cases may be cited.

An engineering firm with an established reputation in another line accepted design work on several highway bridges. The first bridge or two which they designed proved both unsightly and not economical. Subsequently they accepted designs prepared by a bridge company for several other bridges. Later the board by whom they were employed learned that the engineers had accepted a fee for designs which they had not prepared and on which they were really not competent to pass.

In several cases dissatisfaction has been caused by so-called customary clauses in specifications prepared by

engineers. To the lay mind a fee for the "preparation of plans and supervision of construction" includes all necessary engineering after field work and borings. Some engineers accept fees for this work and then write into the specifications clauses requiring the contractors to pay for testing and all engineering help, except usually the resident engineer, and further require the contractor to furnish the resident engineer an office near the job. When some enterprising layman finds this out after contracts are all signed and work has started he is sure that the engineers are not playing fair. The practice may or may not be right, but by the general public it will certainly be regarded as a questionable practice.

Examples of abuses and foolish designing are, unfortunately, not unusual. Bridge engineers occupy positions of public trust, and no effort should be spared to secure proper standing before the public, but until a more concerted and sincere effort is made by engineers themselves to correct abuses and prevent exploitation, only meager results in securing recognition of professional standing may be expected.

There is a strong sentiment throughout the country for organization of government along business lines. Nearly all large, well organized corporations engaged in a business involving engineering have a staff of engineers capable of carrying out practically any work which is undertaken. If special help on any particularly difficult problem is needed, a consulting engineer is called on to assist the regular engineering staff. In this case the consulting engineer is selected and his work is passed upon by men who are qualified to judge such matters. This system has justified itself economically in the business world. Everyone looks forward to the day when government departments will be organized in such a manner that they can be justified economically. It behooves both the state bridge engineers and the consulting bridge engineers to justify themselves from the purely business point of view and to work together in upbuilding the engineering profession.

State Work in Wisconsin Has Improved Bridges and Engineering

BY M. W. TORKELSON

Engineer-Secretary, Wisconsin Highway Commission, Madison

OBJECTIONS made by private engineers and bridge contractors to the practice prevailing in many states of having bridges designed by the state highway departments charge two kinds of waste, that resulting from extravagant notions on the part of state designers concerning the kind of bridge needed, and that due to the incompetence of state designers. When incompetence is alleged it is variously charged to the low salaries paid, to the youth of the men concerned, or to their being state employees and therefore lacking in that progressiveness which is produced only by competitively sharpened wits.

Bad Bridge Work of the Past—Back in 1907, when our state highway department, with advisory powers only, began the work of giving engineering assistance to municipalities desiring to build roads and bridges, both road work and bridge work were in a deplorable state, particularly bridge work, which was not only poorly designed and poorly built but oftentimes carried out with a great deal of plain graft; I know whereof

I speak. Contractors and engineers in private practice had been in the field a great many years and had not improved conditions. I believe it is not going too far to say that the improvement in ordinary highway bridge design is due entirely to the activities of the state highway departments.

It may be true that some of the men employed in state departments are incompetent. It certainly is true that many of them are young and that they are underpaid, but all of these objections can be met. Remove those who are incompetent and replace them with other men who are competent; raise the salaries of those who are underpaid. The youth of the remainder will correct itself if given time. There is no proof that engineers in private practice are any more competent than those employed by the state, and certainly those are rare who have the experience in this particular line that is possessed by any one of a dozen state bridge engineers.

Private Engineers and Lawyers—Engineers in private practice claim that the state department is depriving them of business which is theirs legitimately. These engineers never occupied the field when it was vacant. The ordinary township official never would pay a cent for engineering service; he was skeptical of its value, and distrustful of any individual who came to him standing to profit through the transaction. If the engineers in private practice can go out now and continue to get the business, it is because the state departments have educated the public up to an appreciation of the value of engineering services.

Certainly engineers are not the only professional men that the state employs. One of the constitutional officers is the Attorney General, who employs a considerable staff of men belonging to the legal profession. It has never been thought advisable for the state to farm out its legal business in an attempt to advance the interests of the legal fraternity.

Co-operative Spirit—The Wisconsin highway commission has never solicited the employment of its services. Where local officers have shown the slightest tendency to employ the services of an outside engineer, the state department has withdrawn as gracefully as possible. It has never entered a city even on invitation of the city officials unless it was plain that a refusal to do the work desired would result in a bridge letting under the old conditions, where there would be no standards of any kind whatever. Whenever any engineer in private practice has made a request for any information in the possession of the commission, the information has been cheerfully and immediately furnished. We believe that the more engineering there is on our public work, the better it will be.

Before the state entered the field there were less than a half dozen engineering firms, most of them struggling for a precarious existence. At the present time there is not a single one of the good-sized cities of the state but supports an engineer in private practice, and the most of them are not only existing, they are prospering. And the state highway department in a number of instances has been able to give them business where otherwise municipalities would have undertaken the work in the most unscientific manner. I have in mind a small city which found it necessary to increase its water supply. One of the highway commission's engineers happened to have a conversation with a member of the board of public works and learned that they were just

about to conclude arrangements with a well driller to go ahead and dig a well, on the chance of striking water. Through the representations of this employee of the highway commission, the city council became convinced of the necessity of making some tests before digging the well, and after making investigations of various engineers finally employed a competent waterworks engineer.

Charges of Waste—I do not believe that our highway department has ever constructed any bridges very much in excess of minimum needs. Where we have spent some money in an attempt to produce a pleasing effect in the appearance of the work, this has invariably had the greatest appreciation. I remember one county where we had a hard time getting started, because of a hard-boiled county committee, but the committee was pleased with the first bridge and built several, each an improvement in appearance over the one before; finally, a survey for another bridge came in from that county with the request that I "spread myself" on that job.

I have no doubt that cheaper bridges could have been built in some cases, but this would be through a resort to the time-honored process of skinning the job. And as a man cannot, by taking thought, add one cubit to his stature, neither can he by any mathematical process replace the strength and durability lost by cutting out materials that are needed for an enduring piece of bridge work.

I do not believe that a state department should attempt to monopolize the field, but where it can perform a service it should not hold back. This is the policy we have tried to live up to in Wisconsin and we believe it is the correct one. I think there is a place for the state highway departments and for the consulting engineers as well, and that each will be better off because of the prosperity of the other.

Ten Years' Progress in Lighthouse Engineering

AT THE International Congress of Navigation held in July in London (see *Engineering News-Record*, Aug. 2, 1923, p. 175) one section was devoted to the subject "Principal Advances Made Recently in Lighting, Beaconing and Signaling of Coasts." Two of the papers, abstracted here, indicate the recent developments in this, one of the oldest of the engineer's arts. The first abstract is from a paper by George R. Putnam, United States Commissioner of Lighthouses, and a delegate to the Congress, and the second is by the General Reporter of the Section, D. W. Hood, engineer-in-chief to the Corporation of Trinity House (the British lighthouse service).

United States Developments (G. R. Putnam)—The most important advance in lighthouse work in the United States is the establishment of radio fog signals. The lighthouse service on May 1, 1921, placed in operation three radio fog signals in the vicinity of New York harbor, and a number of additional stations have been established or are now being prepared. Each station during fog or low visibility automatically sends radio signals on a 1,000-meter wavelength, with a distinctive characteristic. Such signals are used by vessels equipped with radio compasses, and reliable results are being obtained.

Bells operated automatically by carbon dioxide gas have been installed on several buoys and at beacons, taking the place of attended aids, at a large saving. The oscillator, a heavy metal diaphragm electrically vibrated, has been tested for use as a submarine fog signal.

The proportion of sirens and diaphones has been increased, and of steam whistles diminished. A number of distantly controlled fog signals have been installed. A gong buoy, provided with four gongs, has been designed to give a signal distinctive from that of the ordinary bell buoy, and is in successful service.

A great advance has been made in lighted buoys, the number having nearly doubled, and the types improved; there are now 638 in service. The most efficient thus far is the type using dissolved acetylene gas. Over 100 outside lighted sea buoys have been established, supplementing the lightships. Tall type iron buoys have been extensively employed in recent years, and can be more easily seen. A small and inexpensive type of buoy built of thin steel plate has been introduced recently to replace wooden spar buoys in channels subject to ice conditions and heavy traffic.

The United States lighthouse service has in commission 117 tenders and lightvessels and steady progress has been made in improving their design. The latest lightvessels are provided with propelling power, usually steam plants burning oil, but Diesel engines are to be installed on several vessels under construction. On new vessels the illuminant is incandescent electric or acetylene and the principal ones of each type are equipped with radio communication. In ten years the number of automatic gas lights has quadrupled, and the number of incandescent oil lights doubled. There has been a large increase of electric lights for subordinate stations and large economies have resulted.

The greatest change in lighthouse construction in recent years has been the more extended use of reinforced concrete, seven lighthouses having been so constructed, one of which is a tower 162 ft. high. This construction has also been used for foundation caissons, for lighthouses and beacons.

The lighthouse service maintains 16,373 aids to navigation, doubtless the largest number under one control. There has been an increase of 28 per cent in ten years, while in Alaska the number has more than doubled.

Summary of Conclusions (D. W. Hood)—As regards the luminary for optical apparatus, authorities are generally agreed that for buoy and beacon lighting, and in many instances for secondary lights, acetylene gas, either in an open flame burner or with an incandescent mantle, is the most popular form of illuminant where electricity is unobtainable. For larger optics an incandescent mantle on a petroleum vapor burner is the most suitable illuminant unless electricity can be readily obtained at reasonable cost, when the incandescent electric filament lamp may advantageously be employed. The need for continued development in the illumination of lighthouses has not in the least diminished, and in no circumstances must it be neglected in the endeavor to develop Hertzian or acoustic fog warnings. The greater its power the more penetrative will be the beam from the lighthouse and the greatest security is afforded to the mariner by providing a signal which he may see and recognize with his eyes.

Little has been said in the reports about the combination of aerial and maritime lights, and your general reporter is of opinion that such a study is worthy of this conference, in order to avoid separate aerial and maritime lighthouses on the coast.

In connection with acoustical fog signals, authorities generally recognize the superiority of the siren or diaphone over other types. Position finding by wireless is destined to be one of the most important navigational aids of the future, whether employed alone or in conjunction with sound to obtain synchronous signals.

Various countries have different direction-finding systems of their own, nevertheless the problem of the most effective type should be investigated not by each country individually, but by common international agreement, and it appears to your general reporter that a system applicable to stations both ashore and afloat which employs a wireless beam whose direction is ascertained by the navigator himself is the primary basis for such investigation and development.

Alumina Cement in France

Use of Quick-Setting High-Strength Cement Is Growing in France—Possibilities of Its Manufacture and Use

BY EDWIN C. ECKEL
Consulting Engineer, Washington, D. C.

THE TERM alumina cement is here used as a convenient designation for the high-alumina fused cements which are now made and sold on a largely increasing scale under the trade names of *ciment fondu*, *Aleiment*, *ciment électrique*, and others. It has the advantage of avoiding any implication as to the invention or ownership of the new cements; and as yet there is a very excellent reason for such carefulness in discussing property rights.

Around 1908 a new type of cement was invented—a cement characteristically very high in alumina, resistant to sea water and to sulphate waters, and hardening with extreme rapidity, so that in a day or two its concrete showed the same results as a normal portland cement concrete after a month or more. In its earliest days its resistance to chemical attack was its chief interest; during the World War it was adopted by the French army for rapid work on gun emplacements and roads; since the war it has been used extensively for ordinary engineering works.

It happened that I was, during the war, in command of a post of which the new fused cements were manufactured and used; and it is probable enough that I was the first American engineer to become acquainted with them. In the summer of 1918 I secured an option on the small available surplus of fused cement, for our own army use; but my immediate superior could not at that time appreciate the advantages of using a quick-hardening product for military uses. Today the situation has changed, and I do not think that any army would dream of using portland cement for front-line work or indeed for any other war-time constructions—provided of course that it had access to a supply of alumina cement.

In the years that have elapsed knowledge of the new product spread gradually, but there was an absolute lack of definite knowledge concerning the actual status of the alumina cement industry in Europe, considered either technically or commercially. There was indeed no lack of publications on the general subject, but these did not, for very good reasons, contain the sort of information which was needed if the developments of the new industry were to be taken up seriously in America. During a recent conference at Le Teil, one of the Lafarge directors noted ironically that the mass of publication was a curious tribute to the public interest in fused-cement, since out of thirty or more articles and papers that had come to his attention, only two were written by men who had ever seen a fused-cement plant, and only three by engineers who had ever used fused-cement in more than laboratory quantities.

Under these circumstances advantage was taken of the fact that examinations of certain European coal and iron fields were desired by one of my British clients, to spend some six weeks of additional time in a study of the status of the alumina cement industry abroad. This was done during May, June and July of 1923, the actual expenses of this part of the trip being paid by a leading American manufacturer of portland cement. The re-

sults were rather better than we had expected, in the way of securing detailed data on all phases of the matter. Much of these data, insofar as they relate to ownerships, manufacturing methods and costs, are of course confidential; but certain matters of general interest, relating to the actual growth of the new industry and to the actual utilization of the new product, are summarized in this article.

Method of Making—To begin with, we may say briefly that the new alumina cements are made by fusing a mixture of bauxite (aluminum ore) and limestone in a furnace, and grinding the product to powder. That is a

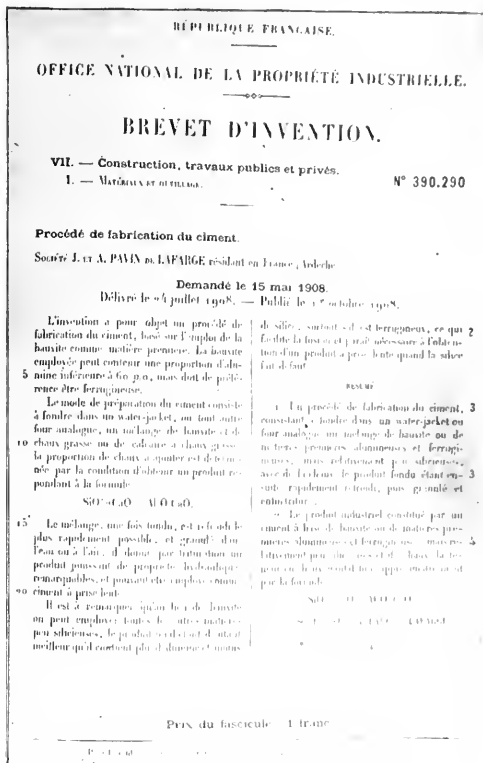

FIG. 1—FACSIMILE OF THE BASIC FRENCH PATENT

Issued in 1908, covering first fused high-alumina cements made at the Lafarge works. This early process has been changed in essential points so that present methods of manufacture are unlike those here claimed.

brief statement of a complicated series of processes, which have evolved from very different beginnings, and which are yet in process of active development. For example, if we build a mill in America I am very sure that it will be markedly different from any existing French mill; I am almost equally sure that within five years we will make even greater changes and improvements. It is therefore merely as a matter of historic interest that I reproduce herewith, as Fig. 1, a facsimile of the original French patent to Lafarge in 1908.

The claims of the patent, translated, are as follows:

1. Process of cement manufacture, consisting in melting in a water-jacket or similar furnace a mixture of bauxite or of material primarily aluminous and ferruginous, but

FIG. 2—CONCRETE PILING FROM ALUMINA CEMENT
These piles, in Holland, are driven three days after casting.

relatively little silicious, with lime, the fused product being then rapidly hardened, then ground and finally pulverized.

2. The industrial product constituted by a cement with a bauxite base or from material primarily aluminous and ferruginous but relatively little silicious, and lime, the content of lime being defined approximately by the formula $\text{SiO}_2\text{CaO} + \text{Al}_2\text{O}_3\text{CaO}$.

The reader must consider this patent with the distinct caution in mind that the alumina cement of today can not possibly be made by following the description of that patent. Not only is that the case, but so far as I can see no commercial cement could ever have been successfully made in that fashion. Fifteen years of hard work have changed plant, processes and product so that those of 1908 are no longer recognizable in the modern industry. The result is that the European alumina cement industry of today is rather a matter of more or less secret processes than of patents.

Production—As to the physical growth of the industry, the best data obtainable indicate an output of some 300,000 bbl. of alumina cement in 1922, of around 350,000 bbl. probable in 1923; and in 1924, with the new mills now reaching completion, a French output of some 400,000 to 450,000 bbl. The significance of these figures can easily be overlooked, if we compare them to American cement outputs; but if we recall that all France does not produce much over six to seven million barrels of true portland cement a year, we see that in four years of actual civil use the new cement has reached an output of about 7 per cent of the total portland output of France.

But though we must admit that the new product can

easily reach an important tonnage figure, we must not conclude that it will replace our portland cements for all uses, or that it will ultimately destroy the present cement industry. There are distinct limitations with regard to the commercial placing of the new product, so that its competition with portland—or rather its replacement of portland—will have certain quantity limits which we can fix with sufficient exactness. The carefully weighed opinions of a number of eminent engineers in France, Great Britain and the United States give results ranging between ten per cent and twenty per cent of the portland output as representing the amount of alumina cement that we can reasonably hope to make and sell within the next ten years.

The extent of the competition will be determined solely by cost. Alumina cement will always be, in most parts of the United States, dearer than portland cement, and in many regions it will be very much dearer. That means that it will be to some degree a specialty product, used for such purposes or under such conditions as will justify its extra cost per barrel. Along sea-coasts and in the alkali region of western Canada and our own western states, alumina cements will be used, provided that they are not too dear, because they are resistant to chemical attack. Elsewhere, on repair or construction work where time is an object, alumina cements will be used so far as their higher cost per barrel is counter-balanced by saving on time, labor and forms. For cement products they have very definite advantages, as permitting prompt shipments.

Summary—It may be possible, in a later article, to discuss some of these uses more fully, with illustrations from actual works. But at present perhaps the best commentary on the situation abroad is afforded by the two entirely separate facts which I now note:

(1) In Great Britain, one of the greatest of the contracting companies is about to undertake the manufacture of alumina cement for its own use and for sale, under one of the two processes that are known. As a corollary, perhaps, one of the greatest of British cement

FIG. 3—SUBWAY WORK IN PARIS WITH ALUMINA CEMENT

manufacturing groups is also about to take up the manufacture of alumina cement, under the other process. In both these cases the necessary bauxite will have

to be imported, so that the incentive to make and use alumina cement must have been very strong.

(2) In Paris, though portland cement is still used on alleys and second-class streets, most of the repair work carried on by the city engineers on first-class streets and bridges, as well as that on the subways, is done with alumina cement. By its use a street intersection can be completely repaired with a three-day tie-up of traffic, as against three weeks or so with portland. In Paris today alumina cement costs almost exactly three times as much as good portland. If the slow and economical French mind can see an advantage under such conditions, we may fairly expect that in the course of time Detroit, Chicago and New York may also find it profitable to save time at the expense of first cost.

Asphalt-Penetration Resurfaces Old Macadam Streets

**Less than a Dollar a Yard Makes Excellently
Surfaced Streets Out of Worn Macadam
in Bridgeport, Conn.**

OLD WATERBOUND macadam streets, dilapidated by modern traffic, are being converted into excellently surfaced thoroughfares in Bridgeport, Conn., by covering them with asphalt macadam. Not including overhead, the cost in 1922 of 140,000 sq.yd. of 3-in. surfacing was 87.1c. a square yard; and this season, with higher wages and prices, the cost, based on figures for a part of the season, is expected to keep well under a dollar a yard. These low costs are being obtained by a combination of contract and day-labor work which also has given rather excellent progress, the work of 1922 having been done in 140 days—an average of 1,000 sq.yd. a day.

At the beginning of operations in 1922 careful plans were formulated for doing the work by a sequence of crews each performing a particular task. These plans were improved and continued in 1923. This year three crews have done the work for which four were employed in 1922 and also the size of some of the crews has been reduced. It is this reduction of force which has enabled costs in 1923, despite higher wages, and prices, to be kept about as low as in 1922 for which detail figures are given in the accompanying table. In the work tabulated, wages were 35c. an hour and stone per cubic yard delivered cost, for 1½-in., \$2.55,

SPRAYING ASPHALT ON STONE SURFACING

and for ¾-in. and ½-in., \$2.65. The quantities used were: 1½-in. a 3-in. layer; ¾-in., 20 per cent, of the 1½-in., and ½-in., 0.1 cu.yd. per square yard. Average costs for the 140,000 sq.yd. were as follows:

Grading	\$0 072
Extra stone in base	064
Stone	290
Asphalt	330
Surface labor	087
Coal for surface roller	004
Heating asphalt in car	015
Office force	009
Total	\$0 871

In all figures the costs of stone and asphalt are contract prices for these materials in place. The differences in price and quantity of asphalt per square yard are in a considerable measure due to differences in the amount of stone per square yard required to bring the old street to surface. In general the old macadam was badly worn and full of pot holes. Its only usefulness was as a base. Reconstruction consisted of four principal processes, grading, placing stone asphalt and finishing, which in 1922 were conducted as follows:

After the engineers had established the new grades the first crew to enter the street was made up of one foreman, about ten men and a steam roller equipped with a scarifier. The street was scarified and reshaped, some of the surplus material being used to fill in the low places. Where the foundation was poor, new stone was added and the whole street rerolled and left in shape 3 in. below the new grade. The finished crown was ¾ to 1 in. to the foot. With a season's experience it was possible this year to reduce the grading gang by two men. This reduction was aided by the plan of not scarifying the center of the old macadam but was chiefly due to greater skill of the foremen following a year's experience.

The second gang, consisting of one foreman and six men, followed with the stone. The stone, trap rock, was unloaded from a barge by a clamshell bucket directly into a hopper, from which it was loaded into trucks. When a truck arrived on the street the tail gate was chained so that it would open about 6 in. The truck would start as soon as the load was hoisted, and in this way the stone was fairly evenly spread; men with forks corrected any unevennesses. The stone then was rolled by another roller which remained with this crew.

* Grading includes removing 6 in. of old macadam and cinder base. ** Grading includes setting curbs and cutting old road about one foot.

Any low places were brought to grade by one or two men who were placed behind the spreaders. As soon as the stone was ready this gang went ahead to the next street which by this time had been prepared by the grading gang.

The third gang was made up of a foreman and ten men, equipped with a steam roller and one of the new White distributors. Asphalt heated in tank cars at the city yard was applied by this gang at the rate of about 1½ gal. to the square yard. Three-quarter and half-inch stone had been placed in piles on both sides of the street about 25 ft. apart, the piles on each side alternating. As soon as the asphalt was applied the ¾-in. stone was spread and rolled. When the stone was thoroughly rolled a second application of about ¾ gal. of asphalt was applied and covered with the ½-in. stone. To keep up the speed of the work it was necessary some days, particularly after a wet spell, to apply 6,000 to 8,000 gal. of asphalt a day.

ROLLING AFTER FIRST ASPHALT APPLICATION

In 1922 a forth crew consisting of three men and a team, was employed to touch up places not thoroughly covered, and to clean up the surplus material, but this season this finishing was made a part of the work of gang three.

The following method adopted by the fireman of the boiler used for heating the tank cars helped to assure a continuous supply of asphalt. The exhaust steam from car 1 was piped to car 2 and the exhaust steam from that to car 3. In this way a full head of steam was on the first car and it was ready for use at any time. The second car was almost ready and the third could be made ready in a couple of hours. All shifting of cars was done at night.

Intelligent scheduling of the sequential operations is required but otherwise the procedure involves no special care or unusual methods. In Bridgeport operations are in charge of City Engineer James McElroy and Director of Public Works George Coughlin. City forces do the work except that, as stated, stone and asphalt are contracted for at a price in place.

Humber River Development Well Under Way

Sir Richard Squires, former premier of Newfoundland, in discussing the proposed power development on the Humber River in Newfoundland, states that the project is well under way and that 2,100 men are now employed on work of a preparatory nature which includes the re-location of a considerable portion of the railroad where it traverses the bed of the proposed reservoir. It is hoped that the work will be well under way by the fall of 1924, and that by the following fall the paper plant will be ready for operation. The total development will be somewhere in the neighborhood of 200,000 hp., a considerable portion of which will be used in the manufacture of pulp and paper, as the new plant is expected to produce 400 tons of paper a day.

New Rose Polytechnic Institute Building at Terre Haute

Engineering College on New Country Site Has Main Building of Unusual Design—Laboratories Not in Separate Rooms—Sale of Old City Property Necessitated Rapid Progress

NOVELTY in design, economy in cost and rapidity in both planning and construction are marked features of the main building completed this year for the Rose Polytechnic Institute on its new site just outside Terre Haute, Ind. This triple combination was effected largely in order to meet financial limitations and emergency conditions. The building, Fig. 1, is the first of a proposed group, but for the present it houses all the departments of this engineering college.

was compelled to move but had no buildings of its own.

At about this time, Dr. Philip B. Woodworth, Dean of Engineering at Lewis Institute, Chicago, was made president of Rose Polytechnic Institute, and the work of providing quarters was his first and most pressing problem. An analysis of the finances showed about \$300,000 available. Dr. Woodworth then called in Mr. Foltz, the architect of the original plan, and between them a design was worked out for one main building

FIG. 1—NEW BUILDING FOR ROSE POLYTECHNIC INSTITUTE

Rose Polytechnic Institute was founded in 1874 by Chauncey Rose, of Terre Haute, Ind., one of the promoters of the Vandalia Line. Until 1922 the institution was located in Terre Haute at 13th and Locust Sts., being housed in a four-story building which was erected in 1876 and had practically no grounds. In recent years the extension of railroad yards in the vicinity has rendered the location unfavorable, while the building was inadequate for the requirements of a modern engineering college and there was no room for expansion. Under these conditions it was decided to remove to a more suitable location in open country which had been provided in 1913 when a site of 120 acres was presented by Anton and Herman Hulman, of Terre Haute, former students of the institution. This site is about 2½ miles from the city, on high ground and fronting on the concrete-paved "National Road," which is paralleled by an electric interurban railway.

A general plan for a group of buildings following somewhat conventional lines for institutions of this kind was prepared in 1916 by Herbert Foltz, architect, and the cost was estimated at about \$800,000. A more elaborate plan was desired by the alumni and was worked out in 1918 by John Van Pelt, of New York, but the estimated cost of \$1,000,000 for the first building was far beyond the reach of the institution. No further action was taken at the time. But in 1918 the institution had sold its building and property to the city for school purposes and early in 1921 the city demanded possession, since it desired to use the building for a vocational high school. Thus the institution

which could be made to serve all purposes for a few years. It is this building which is now completed.

In its interior arrangement, however, the building presents a new departure in the design of educational buildings. In plan the structure is about 150x400 ft. and with the exception of the two end portions, front and rear, it is one story high. The central portion is divided into sections by transverse partition walls of

FIG. 2—DEPARTMENT OF DRAWING AND MACHINE DESIGN

Northeast corner of room. Civil engineering laboratory beyond first low partition. Well diffused light from large windows and skylights. 1-beam at left will carry mezzanine floor for toilets.

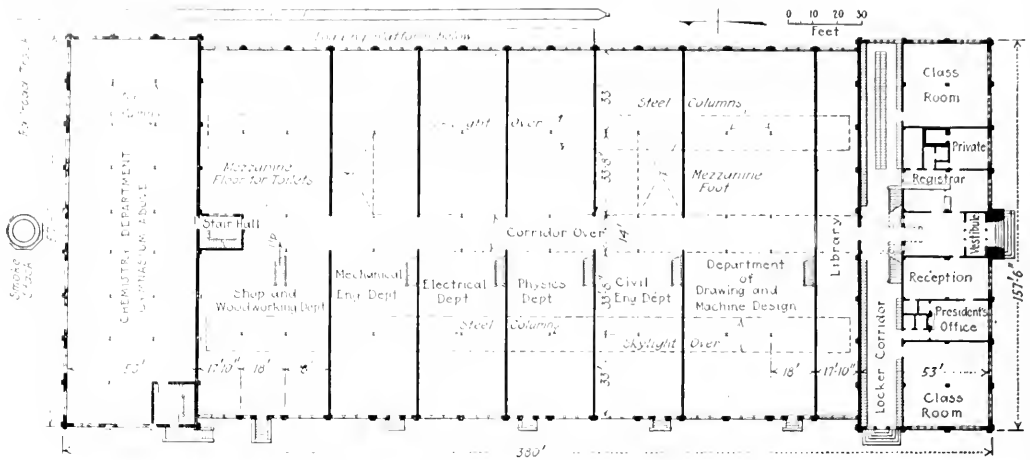

FIG. 3—COMPARTMENT ARRANGEMENT OF LABORATORIES

brick, as shown by Fig. 3 and the accompanying interior views, but these walls are carried only to a height of about 10 ft., so that the upper part of the one-story structure is open from end to end, giving free diffusion of light from the skylights. The first partition at each end, however, is carried somewhat higher, as shown by the drawing Fig. 5 and the view Fig. 6.

It was originally intended that each partition should be continuous between the side walls, forming isolated sections for the laboratories. At present, however, there is a central line of openings permitting direct

communication. Along the center line of the building and about 9½ ft. above the floor is an open gangway or corridor 14 ft. wide, having iron railings along the sides and an iron stairway to each laboratory. In addition, each laboratory has a door in one side wall. In Fig. 6, the first partition, which extends above the corridor, is that between the library and the drafting room. Beyond it, the partitions between the sections or laboratories are about level with the floor of the corridor. These sections, Fig. 3, comprise the following: Library, drawing and machine design, civil engineering,

FIG. 4—CIVIL ENGINEERING LABORATORY

Triangular skylight above. Heavy I-beam beyond first partition wall at right will carry mezzanine floor.

physics, electrical engineering, mechanical engineering, and shop and woodworking department. Of these the drafting and shop department and the chemical engineering laboratory (under the gymnasium) have each 8,000 sq.ft. of floor area; the others have 5,000 sq.ft. each, except the library with 3,000 sq.ft. Under the drafting department is a shooting gallery 36 ft. wide extending the full width of the building.

In the two-story front portion of the building, 54 ft. wide, the administration offices and some of the class rooms are arranged on the first floor and other class rooms are on the second floor, which is about 3 ft. above the level of the longitudinal corridor in the central one-story part of the building. The rear

two-story portion, also 54 ft. wide, has the assembly room or gymnasium on the second floor and the chemical laboratory on the main floor. Beneath the latter are the boiler room and the foundry, each occupying half the width of the building. Owing to the downward grade of the ground towards the rear these two rooms do not form a closed basement but the floor is level with the ground at the rear of the building. Toilet rooms are arranged on a mezzanine floor over

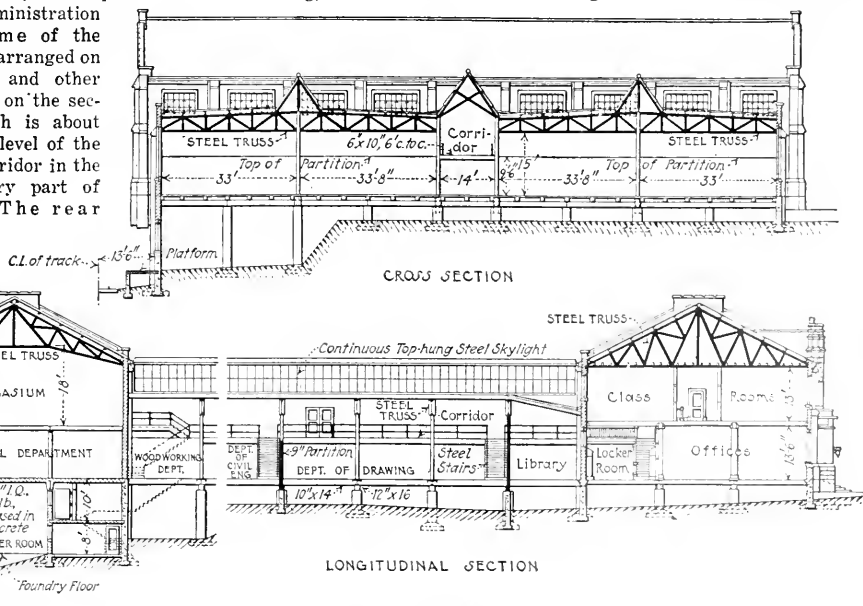

FIG. 5—GENERAL DESIGN OF MAIN BUILDING

a portion of the laboratories and at the level of the corridor. Only one of these floors has been built as yet, but on Figs. 2 and 6 will be noted a heavy I-beam which will support the second mezzanine floor section.

Structural design includes brick walls, steel columns and steel roof framing, with mill construction for the upper floors of the two-story end sections. A reinforced-concrete floor on I-beam framing is provided for the chemical department, but elsewhere there is 23-in. wood mill flooring on joists, generally 10x14-in. and 6 ft. apart, these joists being carried by 12x16-in. girders on concrete foundations. For the corridor the joists are 6x10-in., 6 ft. apart, fitted between the flanges of two lines of 12-in. channels riveted against the interior steel columns. Steel sash forms a large proportion of the side walls, as glazed areas are cheaper than masonry. The partitions and interior facing of the side walls are of dark red face brick and will not be plastered. Transverse steel roof trusses supported on columns in the side walls and on intermediate steel columns in the central one-story part of the building carry three continuous longitudinal skylights of triangular section, with movable panels for ventilation. In this way abundant light is provided, but shades will be needed in sunny weather. The intermediate portions of this roof and also the roofs of the end sections of the building have plank sheathing and composition roofing, which will be covered eventually with red tile. Rough texture brick with white stone trimmings is used for all exterior walls.

Water for drinking purposes is pumped from a driven well to an 80-gal. storage tank. For laboratory and general purposes and for fire protection there is a 200,000-gal. concrete tank or cistern in the basement to collect rain water. This cistern is connected with a small lake 660 ft. distant by a 10-in. cast-iron main, at the middle of which is a sump from which fire engines can draw water. The normal level of the water in the cistern and lake is 13 ft. above that of the boiler room floor. With the power plant located in the building there is a saving in heat loss and fuel cost as compared with an outside power house and pipe tunnel. Two hand-fired water-tube boilers of 160 hp. are installed. Coal is delivered by cars on a railroad spur.

This one building serves all purposes of the institution at present. The next building, as planned, will be Deming Hall, a students' union building, for which \$100,000 was provided in the will of Demas Deming, of Terre Haute.

With the exercise of economy in design and construction, the cost was about \$240,000 for the building and \$320,000 including equipment. In proportioning the cost, the limit of expense (including equipment) was \$3.50 per square foot for the class rooms and drafting room, \$3.80 for the civil engineering laboratory, \$4 for the physics and electrical and mechanical laboratories, and \$5 for the shops and the chemical laboratory. A complete foundry equipment was the gift of E. D. Frohman, Pittsburgh, Pa.

Dr. Philip B. Woodward, president of Rose Polytechnic Institute, is now on leave of absence; Frank C. Wagner, vice-president and professor of mechanical engineering, is acting president; R. L. McCormick, professor of civil and architectural engineering; H. A. Thomas, professor of hydraulic engineering; John White, professor of chemical engineering and C. C. Knipmeyer, professor of electrical engineering.

The Paradox of Hydro-Steam

An Analysis to Show That Energy Generated by Combined Steam and Hydro Prime Movers Can Cost Less Than Either One Separately

BY GEORGE HOLMES MOORE

Senior Electric Engineer, Public Service Commission of Washington, Olympia, Wash.

ONE of the most interesting of the problems encountered in hydro-electric engineering is the computation of the economic size of the steam auxiliary. In fact, certain of the conclusions arrived at by an intensive study of this economic size relation are so unexpected as to seem at first glance preposterous. Thus, when the student has become convinced that hydro-electric energy can be sold with profit at 6 mills per kw., and that steam-electric energy can be so sold at 10 mills per kw., it is extremely difficult for him to conceive that energy, generated by the two methods operating in conjunction, can be profitably sold at 5 mills per kw.

And yet this condition of affairs is by no means impossible of attainment, as a review of such articles as those of Stott, Gorsuch and Baum may suggest. Baum has declared in his paper on the "Economic Proportion of Hydro-Electric and Steam Power" (A. I. E. E., *Trans.* 1918, p. 1471), that: "It is, of course, well known that steam power is usually less expensive for low load factors than hydro-electric power, and that the latter becomes economical only when the load factor is favorable."

Another author in an article directing attention to "The Possibilities of Hydro-Electric Power in the Pacific Northwest" (*Engineering News*, Vol. 73, p. 342), shows that: "The immense preponderance of water-power drive throughout the Pacific States admits of but one conclusion—the local superiority of water over steam. There is little room for doubt as to the economic standing of the two prime movers on the Pacific Coast"; from which it is readily apparent that seemingly contradictory statements may emanate from trained investigators, even in the same locality and in the same field of research.

However, the paradoxical condition can—and doubtless does—exist. Electric energy can, in certain instances, be produced at a lower unit cost by hydro and steam stations operating in parallel than by either when operating alone. And it is the purpose and intent of this paper to present, as simply as may be, those essen-

FIG. 1—DAILY LOAD CURVE FOR A REPRESENTATIVE CITY LIGHT PLANT
Composite mean form for yearly load factor of 50 per cent.

FIG. 2—ANNUAL RECORD OF STREAM FLOW

tial elements of control which, at least for Pacific Northwest conditions, dictate the economic proportionment of hydro-electric and steam-electric generating plant capacities.

Two of the most important of the basic data required for the analysis of a power stream destined to supply any particular distribution system are: 1. Annual System Load Curve and 2. Annual Record of Stream Flow.

System Load Curve—In Fig. 1 is presented a composite mean form of daily load curve as obtained from a certain large system from a record extending over a number of years. This particular annual load curve has a load factor of 50 per cent, so that a 100,000 kw. power station supplying it would have an annual output corresponding to 50,000 kw. continuous; or an annual total of $50,000 \times 8,760 = 438$ million kw.-hr. per year.

Annual Record of Stream Flow—Of the many surprising elements disclosed by the careful hydrographic study of a power stream, there are three which may be said to control. These are respectively:

- (a) Minimum Stream Flow
- (b) Storage Requisite for Daily Regulation
- (c) Storage Requisite for Annual Regulation.

Of these three, the one first sought and most commonly used as a basis for station capacity estimate is that of Minimum Flow, and just because the commonest hydro-electric installations are those designed to operate at full capacity during the months of Minimum Flow, the paradoxical inter-relation of hydro and steam has not yet received the attention its importance merits.

Daily Regulating Storage—An analytic consideration of Fig. 1 will prove that the station capacity which may wisely be installed upon any given power stream can be exactly doubled if sufficient storage can be secured to provide daily regulation of the stream flow. Daily Regulating Storage may be here defined as that volume necessary to change the normal flow so as to conform to the daily load requirements of the system supplied. The acre-feet of storage required for this purpose is relatively small, but, if the average stream flow will generate 50,000 kw. continuously, such storage will allow of the installation of a 100,000 kw. plant under the load conditions shown in Fig. 1.

Further study of this load curve discloses that the

energy necessary for load between 50,000 kw. and 100,000 kw. is only one-sixth of that necessary to generate 50,000 kw. continuously, so that in this case the reservoir volume for daily regulation would be one-sixth the volume of daily stream flow.

Economic Utilization of Stream Flow—Let us assume that the load demanded for the curve of Fig. 1 is supplied by a power station located on a stream whose Annual Record of Flow is that shown in Fig. 2. If the static head of this development is 600 ft., each cubic foot per second of water should produce 40 kw. of continuous output; or, on a daily load factor of 50 per cent, it should produce 80 kw. at time of peak if daily regulating storage is available.

Let us assume that the reservoir volume developed is sufficient for daily regulation of the average annual flow as shown in Fig. 2. The 1,250 sec.-ft. of mean flow will then be just sufficient to drive a 100,000-kw. hydro station with an average output of 50,000 kw. continuously. From the foregoing, the storage necessary in this case is:

$$\begin{aligned} 0.165 \times 1250 \times 60 \times 60 \times 24 \\ = 17.82 \text{ million cu. ft.} \\ = 409.09 \text{ acre-feet.} \end{aligned}$$

This reservoir volume would be sufficient to store the Minimum Flow of 400 sec.-ft. for a period of:

$$\begin{aligned} 17,820,000 \div (400 \times 60 \times 60) \\ = 12,375 \text{ hr.} \end{aligned}$$

From which it follows that, if the steam auxiliary can supply the demand during 12,375 hours of the lightest load, enough water will accumulate in the reservoir during that period to operate a 50,000 kw. station during the hours of peak load, and thus to supply all demands between 50,000 kw. and 100,000 kw. during that time.

Adding to this 50,000 kw., the 16,000 kw. available from the Minimum Flow of 400 sec.-ft., it becomes evident that only 34,000 kw. of steam auxiliary need be provided in order to supply 50,000 kw. continuous and 100,000 kw. peak even under the limiting condition of Minimum Stream Flow.

Hydro-Steam Cheaper than Hydro or Steam—It now remains only to demonstrate the major proposition advanced herein, namely: that energy produced by the combination of hydro and steam is cheaper than that produced by either hydro or steam when operating alone.

From the foregoing, it is evident that a 32,000 kw. hydro station is the largest that should be installed on the given stream under the conditions as assigned, if no steam auxiliary is provided; and the following tabulation presents an estimate of installation and operating

FIG. 3—INSTALLATION COST OF HYDRO-ELECTRIC PLANTS

Curve showing decrease of unit cost and annual charge with increase of installed capacity.

FIG. 4—ECONOMIC COMBINATIONS FOR HYDRO-STEAM ELECTRIC PLANTS

	Hydro	Steam
Cost per Kw.:		
20,000	\$300	\$100
30,000	250	..
40,000	200	..
100,000	150	100
Fixed Charge:		
Interest	6%	6%
Depreciation, etc.	4%	6%
Fuel charge, oil @ 200 kw.-hr., per \$2.50 bbl.		
Load factor yearly, 50% installed.		
Load curve, typical city light plant.		

costs for a 32,000 kw. hydro station supplying a demand whose load factor is 50 per cent. Such a load will require an energy production equivalent to a continuous average of 16,000 kw. throughout the year.

Installation cost of hydro is assumed to vary as shown in Fig. 3, being \$400 per kw. installed for a station capacity of 10,000 kw., and decreasing to \$150 per kw. for an installation of 100,000 kw.

Installation cost of steam is assumed constant at \$100 per kw. installed, regardless of the station capacity.

Base data for the computation of annual operating expense are given in Fig. 4, among which that of oil at \$2.50 per bbl. will be revised to \$1.40 per bbl. in a later study.

Applying the data of Figs. 3 and 4, the following comparative tabulation results:

Item	Hydro	Steam
Installation cost (32,000 kw.)	\$7,744,000	\$3,200,000
Annual fixed charge	\$774,400	\$384,000
Annual fuel charge	981,120	1,752,000
Total annual charge	\$774,400	\$2,136,000
Annual kw.-hr. ($\frac{\text{kw.}}{2} \times 8,760$)	140,160,000	140,160,000
Annual cost per kw.-hr.	\$0.0055	\$0.0152

Changing only the item of fuel from \$2.50 to \$1.40 per bbl., and adding another column for a hydro steam plant of the size indicated, we obtain the tabulation given below.

Item	32,000 Kw., Hydro	32,000 Kw., Steam	32,000 + 18,000 Kw., Hydro-Steam
Installation cost	\$7,744,000	\$3,200,000	\$9,344,000
Annual fixed charge	\$774,400	\$384,000	\$966,400
Annual fuel charge	981,120	1,752,000	1,533,600
Total annual charge	\$774,400	\$1,365,120	\$1,119,700
Annual kw.-hr. ($\frac{\text{kw.}}{2} \times 8,760$)	140,160,000	140,160,000	219,000,000
Annual cost per kw.-hr.	\$0.0055	\$0.0096	\$0.0051

A word of explanation as to the reason for choosing an 18,000 kw. auxiliary is due just here: Referring to the load curve of Fig. 1, it will be found that, if the peak load is taken as 50,000 kw. instead of 100,000 kw., the annual daily average will be 25,000 kw., and this will, in the 8,760 hours of a year, amount to the 219

million kw.-hr. of column 4. Also, closer inspection will reveal that all loads above 64 per cent of the peak, (which 64 per cent is, in this case, 32,000 kw.), will demand only about one-tenth of the annual energy, or 219 million kw.-hr., to be furnished by the steam plant. This energy, at 7 mills per kw.-hr., will produce the fuel charge of \$153,300 as given in column 4.

Even this is not the most favorable proportionment that could be obtained, since it entails an annual load factor for the steam plant of nearly 14 per cent, whereas a 10 per cent load factor for the steam auxiliary would probably result in a greater economy of output. This would probably decrease the 18,000 kw. as here chosen, but the resulting decrease in energy cost is unimportant here.

From which it is evident that the paradox—which Webster defines as "something apparently absurd or incredible, yet true"—really does exist. Not only does a carefully chosen proportion of steam to hydro cheapen the unit cost of the energy produced, but also it makes possible the conservation, by use, of enormously increased quantities of power stream energy.

Thus, in the case cited, it will be found by further analysis that 32,000 kw. is only, in a manner of speaking, the beginning of the installed capacity that may economically be installed on the stream as chosen.

The available storage will usually be far greater than that requisite for daily regulation, and probably will be sufficient to materially augment the Minimum Stream

FIG. 5—ECONOMIC CONTROL CURVES

Showing variations of cost, revenue and waste, as the installed plant capacity varies from 0 to 100 per cent of stream energy capacity. It is assumed that, under a static head of 600 ft., each sect. will produce 40 kw. continuous and 80 kw. peak, under an annual load factor of 50 per cent. Also, that, of the 4,380 kw.-hr. generated per year by each kw. of plant capacity, 4,000 kw.-hr. will be sold.

Flow. So that the installable hydro station capacity will increase from 32,000 kw. toward 100,000 kw., and sometimes above that figure.

Indeed, if we define the economic control for power stream development as "the cost of generated energy plus the revenue equivalent of wasted stream energy," it will be seen from Fig. 5 that this sum in "millions of dollars per year" is a minimum only when the stream is developed to its ultimate capacity. Which statement may be, itself, a paradox.

Failure of Apishapa Earth Dam in Southern Colorado

Structure 115 Ft. High Above River Bed Goes Out After Stream of Water Breaks Diagonally Through Upper Portion

With Telegraphic Reports from Special Correspondents

THE APISHAPA DAM, near Fowler, Colo., an earth structure 115 ft. from stream bed to dam crest, failed on Aug. 22, with a water level behind the dam variously reported as from 2 to 3 ft. below the spillway and 10 to 13 ft. below the crest, the water being some 10 ft. higher than it had ever been before. Leaks attributed to settlement cracks had been observed a year ago. Just before the failure a crew of men under the chief engineer of the Apishapa Consolidated Irrigation Co., owners of the dam, had, as was thought, practically stopped the leaks. These leaks were at each end of the dam, about 25 ft. below the crest.

Maximum Embankment Section, through Stream Thread

MAXIMUM CROSS-SECTION OF APISHAPA DAM IN

The dam was 585 ft. long at the crest and 300 ft. at the bottom. The thickness at maximum cross-section was 594 ft. The crest of the dam as built is at the top level of the

SOUTHERN COLORADO AS COMPLETED IN 1920.

The dam was 585 ft. long at the crest and 300 ft. at the bottom. The thickness at maximum cross-section was 594 ft. The crest of the dam as built is at the top level of the

Warning of failure came when water was seen entering the dam at the water surface at one end, to be followed soon afterward by a discharge at the other end, some 25 ft. lower down or about 35 ft. below the crest. The water level fell slowly for an hour, then more and more rapidly until within three hours the reservoir had lost 18,000 acre-ft. of storage. Meanwhile the dam, except for portions at either end (and perhaps some of what was under water), had gone downstream with the flood.

The dam, which was described at length in *Engineering News-Record*, June 16, 1921, p. 1030, by Clair V. Mann, engineer in charge of construction, and also of re-design, was completed in September, 1920. It was designed to guard against underflow along either the earth on which it rested or along the rock below, and drains had been provided in the rock fill beneath the downstream third of the dam. The original plan, Mr. Mann stated in his article, was to build "a concrete cutoff wall extending down to bed rock, and up from stream bed a height of 50 ft.," but as this was not "within the company's means," the cutoff just described was substituted. Mr. Mann also states in his article that as originally planned the dam was to have been carried 120 ft. above the stream bedrock but that

"financial considerations" restricted the height to 115 ft., thus leaving the crest of the dam "only 7.8 ft. above the spillway crest, and the writer [Mr. Mann] considers this insufficient margin for safety."

Mr. Mann is on record even more specifically than this as to this danger. In a protest and warning printed on the official record plans filed in the office of the state engineer of Colorado (the plans being dated July 15, 1919; the protest Sept. 18, 1920; and the approval of the plans as of March 21, 1921, being signed "Addison J. McCune, State Engineer"), Mr. Mann mentions "a discrepancy between the elevations of the spillway" and the "crest of the dam as staked out by Chase & Barto and as shown on their plans." He says:

The changes on this sheet are due to the fact that the undersigned assumed the previously mentioned plans and surveys were substantially correct, and, because both time and help were limited in making surveys for the revised plans; did not make the revised survey of spillway until after construction was well under way. The above noted discrepancy was then found, and to correct it and make the dam safe, the changes shown on this sheet were made and staked out on the ground by me, in accord with the specifications, and well in advance of construction at the levels involved. Neither the company nor contractor would agree to the change although fully advised that the dam

would settle perhaps 5 ft. after filling, and that with much spillway discharge and simultaneous south winds, the dam will be overtopped. The state engineer was likewise fully informed as to all facts in the case, but required no change. I absolutely decline to accept any degree of responsibility for any future damage the dam may suffer by reason of failure of company or others concerned to have indicated changes made when they were possible, or in the future, nor for failures to build rockfill toe or line tunnel as provided for in my plans and specifications.

While awaiting fuller details there are given below telegraphed reports on the failure from A. J. McCune, state engineer of Colorado, who was consulting engineer for the dam when it was built; from John E. Field, representative of Mr. McCune at the scene of the failure; and from O. N. Floyd and Barton M. Jones, Pueblo representatives of the Dayton-Morgan Engineering Co., who visited the scene of the failure:

Mr. McCune—Dam break due to settlement cracks. Water was 2 ft. below spillway and 13 ft. below dam crest at time of break. Break occurred at 3 p.m. At 5 p.m. had discharged 18,000 acre-feet. Apishapa Creek at Arkansas River, forty miles below dam, discharged about 60,000 sec.-ft. and was 3 ft. below flood crest of 1921; at La Junta was about 14 ft. below 1921 flood.

John E. Field—Failure probably due to settlement cracks. Previous maximum filling, 20 ft. below spillway. No lives lost. Financial loss about \$1,000,000.

O. N. Floyd and Barton M. Jones—Dam 70 miles south-east of Pueblo and 35 miles south of Fowler. Outlet tunnel 10 x 11. [10 x 10½ ft., according to Mann article, and built to deliver 2,000 sec.-ft. to satisfy prior water rights], through rock in West bluff, partly lined with concrete. This tunnel, with gates and tower, undamaged.

Spillway 10 ft. [Mann article, cited above, says 7.8 ft.] below top of dam and one mile from dam, through natural gap. At time of failure water was stationary 10½ ft. below top of dam. Previous high stage, which occurred last winter was 10 ft. lower.

Flood caused by cloudburst in headwater region without excessive rains near basin.

Fill placed by wagons in layers of 1 ft., sprinkled and rolled with smooth concrete roller weighing one ton per foot width. Lower 60 ft. built of earth taken from valley bottom, balance taken from high ground east of dam. Small part of valley material was left in west upstream

at the west end. A caving in of the top soon exposed the diagonal flow through the dam. This open channel flowed several minutes before the general failure began.

The workmen left the dam at 3 p.m., when the flow was beyond control. At 3:45 the water surface in the reservoir bed had fallen 2 ft.; at 4 p.m. it had fallen 3 ft. and during the next thirty minutes it dropped 25 ft. This 25 ft. represented a storage of 9,300 acre-feet or half the original contents, discharging at an average rate of 225,000 sec.-ft. During the next fifteen minutes the water level dropped 13 ft. which left a storage of 3,600 acre-ft.

The narrow rock canyon continues about a mile below the dam. At a point 1,000 ft. below the dam the maximum high-water mark was 45 ft. above the creek bed. Below the canyon the flood plain widened to a mile and a half in some places with a maximum depth eleven miles below the dam of about 15 ft. The flood reached this point at 5:20 and at 8 o'clock it reached the railroad bridge near

Photographs from John E. Field

VIEWS OF APISHAPA DAM AND RESERVOIR, COLORADO, BEFORE, AT INCEPTION OF AND AFTER FAILURE

1. Part of upper slope with water surface at about 76 ft. as shown by gage on outlet tower at left. Gage reading at time of break was 83 ft.
2. Water coming from lower slope of dam, near west end, at beginning of failure, about 3 p.m., Aug. 22.
3. After the failure; looking downstream. Remains of dam
4. East end of what was left of dam after failure, with concrete cutoff wall that was carried up and into canyon side and projected into earth dam. Also shows cast-iron drain pipe.

toe and appeared to be fairly well saturated. Small amount of upland material left at each end of dam appeared to be finely powdered, earth containing some sand and gravel. Water had penetrated this material 5 ft. at a depth of 20 ft.

Dam was being watched by the owner's chief engineer, who had a large crew on hand because of small leaks underneath at each end, about 25 ft. below the top. These leaks had given trouble last year, but had been practically stopped before the failure occurred. When all danger was considered past a large flow of water was discovered entering the dam at the water surface near the east end. A few minutes later a muddy stream the size of a man's body burst from the downstream slope near the west end at about 35 ft. below the top of the dam. In spite of all efforts to stop the inflow it increased very rapidly and it was soon apparent that the water entering at the east end was the same water coming out of the downstream slope

Fowler, 35 miles below the dam. Here the railroad embankment acted as a retarding dam and reduced the flow, already greatly modified by the valley storage, to 50,000 sec.-ft. The flood wave continued down the Arkansas River at about four miles per hour.

No loss of life has been reported and the property damage [below the dam?] is much less than would be expected. None of the numerous diverting dams along the Arkansas River was destroyed.

The foregoing information was gathered from personal inspection of the site of the dam and valley and from interviews with persons who saw the failure and some who were familiar with construction of the dam.

The dam was the property of Apishapa Consolidated Irrigation Co. It was constructed under the general supervision of the state engineer and it is apparent that care was exercised to obtain a first-class job.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Am. Soc. C. E. Nominations

Sir—May I call your attention to one error in the report printed on p. 319 of *Engineering News-Record* for Aug. 23, showing the result of the second ballot for official nominees of the American Society of Civil Engineers, canvassed Aug. 15?

In District 1 the two candidates for the office of Director were both to be voted for, as there are two vacancies to be filled. Paul G. Brown received 455 votes out of a possible 551—the total number of members who voted in that district. Thaddeus Merriman received 513 votes from the same 551 members. Since these men were not in competition with each other, the addition of the figures to show a total of 1,066 is misleading.

JOHN H. DUNLAP,
Secretary Am. Soc. C. E.

New York, Aug. 24.

Street Docks for Parking Cars

Sir—Referring to the enclosed clipping, and the author's suggestion that "traffic officials take the attitude that parking spaces should be so arranged as to accommodate the greatest number of cars," etc., why not, instead of painting white lines on pavements (which few drivers heed when parking) build out from the curbs at the proper angle and at curb height, concrete barriers, thus giving the curb line plan a "harbor appearance" like that of the Hudson and East River pier lines, only with greater uniformity. These permanent "berths" can be rented by the city authorities to motorists on some similar basis to that charged by pier-owners for the use of their piers by the ships which dock at them. Car owners who want to store their cars all day in front of some one's place of business, to the latter's inconvenience, and perhaps his financial detriment, would pay a storage charge in proportion to the time they occupied the berth, and thus a premium would be put on getting out quick, and keeping on the move for there would be no "free parking" in the congested area or district. Of course the rates would also have to cover a sort of "time-lock," like a slot machine, on the curb. Man drives into the berth, slips the chain of the time-lock through front wheel and hooks the free end into its proper place in the time-lock which starts the time mechanism, comes back in an hour, wants to go, dial shows amount due, say 50c. puts in money same as in telephone, chain releases, and he can get away. The "perambulating inspector" finding anyone using berth without tying up to the time-lock has the cheater arrested and fined for beating the city out of its revenues, etc. Thus we have it all simplified—the congested area is relieved of the "dead-storage" problem, and the expense of supervising "limited" parking is borne by the man who causes the expense, etc. (You sell the idea to the city authorities and we'll organize a company to build the time-lock devices and we'll either sell them on a royalty basis or rent them for a fixed annual fee, same as slot machines are handled.) Insurance companies ought to like this because it would reduce the stolen car risk, and I'll bet there's many a car owner willing to pay for a place to park.

(No! This isn't the result of "the hot weather," and I own a car, too.) But we both know of men who have made a lot of money out of less worthy ideas than this, and maybe some one will out of this. It has its possibilities.

Seriously, though, something ought to be done to straighten out this parking problem. Yes, it's getting so that the average motorist in a big town is as bad off as

Noah's dove, which we are told found no place to park and so returned to the home garage. So if you, in your search for solutions to traffic engineering problems, can use this idea—go ahead.

A. NONYMOUS.

Washington, D. C., Aug. 16.

Using a Bridge to Brace Its Abutments

Sir—Some fifty or sixty years ago William F. Ellis, of Ashland, Mass., widely known in railway engineering circles, was chief engineer of a western road. He once had occasion to change the plans of a road crossing from grade to overhead, which in turn called for changing a near-by river bridge from through to deck construction. The bridge had a span of about 200 ft. One of the resident engineers presented a very low estimate of the cost of this change, and in explanation produced a sketch which showed retaining walls about 20 ft. high, so thin as hardly to carry their own weight. The resident engineer's attention was called to the doubtful strength of the walls, and their relation to the thrust of the embankment. He said in explanation, "The end of the deck bridge will take care of that, all right." Mr. Ellis looked at his assistant for a moment rather sternly, and then said, "Young man, I am unfamiliar with your practice out here; but in my part of the country abutments are built to support bridges. Not a bridge can be found carrying its own abutments."

Shelter Island, N. Y., July 21.

Highway "Distant" Signals at Crossings

Sir—In Ohio, and elsewhere as far as my observations have been made, the danger signals along the highway have in general corresponded with what in railway signaling is known as the "home" signal. Apparently the idea of placing a variety of danger signals very near the railroad has held too long. The vehicle on the pavement is no longer horsedrawn, and the old crossarm or its nearby assistants do not inform the motor vehicle sufficiently in advance.

My proposition is to place one, two or three series of "distant" signs for the motor driver to read. These may vary with circumstances but where possible the arrangement would be to place one series of three signs, one 500 ft., another 1,000 ft. and the third at 1,500 ft. from the track. Each series should consist of three separate signs with all lettering horizontal, the signs to be placed generally on the right side of the road, or where lights strike them at night; the first sign to read "DANGER"; the second "RAILROAD" (if two railroads or more are parallel or cross the highway near each other this would be varied as "3 RAILROADS"); the third sign to read "1,500 FT." if three series as above indicated were used.

The individual signs should be not closer than 50 and preferably 75 ft. apart (or more) and the sign carrying the distance information should be that distance from the first railroad to be crossed.

I suggest signs having letters 24 in. high and the individual words or phrases to measure 10 ft. long. The signs should therefore measure 36 in. by 12 ft. The character of letters should be plain capitals with from 4 to 5½-in. stroke.

White backgrounds with black letters on wooden signs, made with a slight water-table above and half-round strip on sides and bottom, and supported by two posts of durable wood but light section, would in general be the construction. The signs should be erected so as to clear from 48 to 60 in. above the pavement (clearing ordinary weeds and snow-drifts) but in special places they might be much higher or even lower than the highway, depending upon gradients and positions of the light shafts.

I have recently painted on highways danger signs of the above description with letters 24 in. high and of 5½-in. stroke, but abbreviating the "RAILROAD" to "R.R." or "2 R.R.'S," etc. There is no way of permanently marking these letters on the pavement however, and the zone-marking

white paint discolors to a yellow if placed on tar. For this reason I propose the sign on the side of the road, wholly free from advertising or state-highway marking, and in two or three series as stated above.

The Ohio highway department has painted white strips to correspond with two rails across the highways at certain places. This I believe is good practice but would be better if the strips paralleled, as nearly as practicable, the railway. One would then know in what directions to look for a headlight.

I am offering this plan to meet the grade-crossing menace; it is a "distant" signal to careful and careless alike whether driving at 15 or 50 miles per hour.

It is not intended to replace the home signal or signals, stationary, reflecting, swinging, flashing or bell ringing. I believe, however, that the plan contemplates an inexpensive addition to existing signals at a fair percentage of the grade crossings.

Columbus, Ohio,
Aug. 16, 1923.

V. A. EBERLY.

Action of Frost in Heaving Concrete Piers

Sir—Last March we were notified by the manager of our Montreal plant that one of the concrete piers supporting a shaft and hot air duct outside the main motor house had been raised 1½ in., apparently by frost action. This pier had been constructed during the previous summer. It was 7 ft. long and tapering in section from 2 ft. wide at the base to 1 ft. wide at the top, and set in the ground to a depth of 5 ft. 3¾ in. as shown in the accompanying sketch. As the form of the pier was intended to prevent just such heaving by frost, and as the depth of the bottom was considered to be well below the usual frost penetration, I immediately had an investigation made to determine if possible the cause and to see just what had occurred. The ground in which

SECTIONS THROUGH CONCRETE PIER TO ILLUSTRATE EFFECT OF FROST ACTION

the pier was built is a heavy, tough, sticky clay of a grayish brown color, frequently known as gumbo. At this point it was kept well saturated by the drip from a nearby steam trap which was unable to escape on account of frozen ditches.

In digging down alongside of the pier we found the ground frozen solid until it was almost like sandstone to a depth of 4 ft. 1 in. below the surface. Beyond that point there was no frost and the wet, sticky clay could be scooped out by hand. Underneath the pier we found a vacant space 1½ in. deep which clearly indicated that the pier had been raised bodily for that distance above its original bed.

The theory that we have to advance is as follows:

Imagine the ground to be laminated, and for the sake of argument we will say each layer of earth is 1 in. thick. As the winter advanced, layer No. 1 at the surface of the ground froze and at the same time it froze to the sides of the pier. As winter advanced still further, layer No. 2 (which was also saturated with water) froze, and, in freezing, it expanded and pushed layer No. 1 up, breaking the bond between layer No. 1 and the sides of the concrete pier. So this action proceeded, until the ground was frozen to a depth of possibly 3 ft. Then a thaw occurred. During the thaw the melting snow on the surface then found its

way down between the frozen ground and the sides of the pier. Immediately following the thaw, which only lasted long enough to melt the snow on the surface of the ground, came freezing weather, at which time the water between the frozen ground and the sides of the pier froze solid, and bonded about 3 ft. of frozen earth to the sides of the pier. As the cold weather continued, this freezing action was repeated, but this time when a layer of earth an inch thick would freeze and expand, instead of breaking the bond between the frozen ground above and the sides of the pier, it would lift both the frozen earth above it and also the concrete pier, as the bond between 3 ft. of frozen ground and the concrete pier was greater than the weight of the pier and the frictional resistance of the 1 ft. 3¾ in. of soft clay against the sides of the pier under the frozen ground. As the freezing continued, this action was repeated until the pier was finally lifted 1½ in. out of the ground.

The fact that the pier did not heave out of the ground until the end of February or March tends to confirm this theory.

One often reads specifications to the effect that all foundations shall extend below frost line. Such a specification is undoubtedly satisfactory in the case of a heated building, but in the case of isolated piers and non-heated buildings I am convinced that such wording of specifications allows for very little protection against heaving.

In view of the fact that I have not been able to find any satisfactory explanation of frost action on foundation piers in textbooks and technical magazines, I am forwarding the results of our investigation and our conclusions in the hope that you will give us your views on the subject.

Montreal,
June 6, 1923.

L. DEB. MCCREADY,
Chief Engineer,
Canadian Explosives, Ltd.

[In considering this case of frost action on foundation piers, described by Mr. McCreedy, it should be noted that the pier in question is unusual in that it supported only a light timber framework carrying a 3½-in. shaft and a 10-in. hot air duct inclosed in a light wooden box. Consequently the heaving action of the frost only had to raise a little more weight than the weight of the concrete pier itself. For such piers a spread footing with the top of the spread footing well below frost line, properly reinforced for tension between the body of the pier and the spread footing, would probably prevent heaving. In constructing such piers the surface area exposed to the freezing ground should be reduced to the minimum.—EDITOR.]

A Remedy for Wearing of Earth Shoulders

Sir—A subject of much interest is that of a method of preventing the earth shoulder from washing or wearing away from pavements. Everyone knows the inconvenience and danger to traffic caused by this condition yet its elimination does not seem to the writer to present economic or structural difficulties.

This condition can be eliminated without additional cost above that estimated for the pavement. Suppose it is decided that an 18-ft. pavement will accommodate traffic over a certain route and that the pavement is to be of concrete. If instead of constructing a concrete pavement 18 ft. wide a width of 12 ft. were constructed of concrete in the middle of the roadway, and this flanked on both sides by clay-bound or water-bound macadam of such width as can be built with the money saved by cutting the concrete down to 12 ft., a pavement could be constructed of sufficient width to be safe without costing any more than the standard 18-ft. pavement. The concrete section would accommodate the traffic in a single lane and the macadam sections would be used in meeting and passing.

E. D. Fry,
Resident Engineer, South Carolina
Highway Department.
Columbia, S. C.,
Aug. 23, 1923.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

"Harding Highway" Is the Name Given by the Board of Chosen Freeholders of Salem County, New Jersey, to the Pennsgrove-Malaga road, in commemoration of the late President Harding, who last spring passed over this road enroute from Washington to Atlantic City.

Surveying for a Branch Line of the Canadian National Rys. from Brule, Alta., to Grande Prairie, a distance of 200 miles, has been started. This will give settlers in the Peace River country a direct connection with the Pacific and will tap important coal deposits on the Smoky River, the Bay River and Sheeps Creek.

Upon the Recommendation of its engineering staff, the Federal Power Commission has approved the application of the Pike Rapids Power Co. for a license to develop power at Pike Rapids on the upper Mississippi about 70 miles north of St. Paul and has rejected the conflicting application of the Little Falls Water Power Co. The project will develop approximately 24,000 hp.

Addition of a New 10,000-k.w. turbine unit at the plant of the Oklahoma Power Co., on the Arkansas River, across from Tulsa, at an expense of \$600,000, will bring the total capacity of the plant to 30,000 kw., according to Fred W. Insull, president of the Public Service Corp. of Oklahoma. Work on the new installation will start within a few weeks.

Contracts for Two More Hydro-Electric developments in Canda have been awarded. That for the Southern Canada Power Co.'s new 30,000-hp. plant at Hemming's Falls, near Drummondville, Que., has been awarded to the Foundation Co. of Canada, Ltd., and that for the Hollinger Consolidated Gold Mining Co.'s 25,000-hp. plant at Island Portage on the Abitibi River in Northern Ontario to Sir Wm. Arrol, Ltd., of St. Catherine, Ont., for the dam and power house, to the Dominion Engineering Co. for turbines and to the Canadian General Electric Co. for generators.

The Alaskan Engineering Commission, the organization which constructed the government railroad in Alaska and now has charge of its operation, will hereafter be known as the Alaska R.R., according to an announcement of the Department of the Interior. This change will eliminate considerable confusion which now exists due to the similarity of the two names, the Alaskan Engineering Commission and the Alaskan Road Commission; the latter commission being under the supervision of the Secretary of War and charged with the construction and maintenance of wagon roads in Alaska.

Part of Nutley Zoning Ordinance Held Unconstitutional

Following closely on a decision of the New Jersey Supreme Court, by Chief Justice Gummere, that a prohibition of two-family dwellings in the zoning ordinance of Westfield, N. J., is illegal (see *Engineering News-Record*, Aug. 16, p. 281) Judge Katzenbach of the same court has ruled against the portion of the zoning ordinance of Nutley, N. J., under which a building permit for a store in a restricted residence district was refused. In essence, the last-named judge held that the property owner would be deprived of a constitutional property right under an interpretation of the police power which is contrary to the opinion of the judge as to what that power includes.

Toronto Faces Large Expenditure for Improvements

The city of Toronto, Canada, has just been appraised of the fact that during the next few years it must face an outlay of approximately \$60,000,000 for special purposes. The information was contained in the annual report of Finance Commissioner George H. Ross. Included in the prospective items of expenditure were: Money to be paid for the street railway which was recently taken over by the corporation; the city's share of the cost of a railway viaduct on the waterfront and the grade separation in the northwest section of the city; consolidation and extension of the municipally-owned light and power system; extensions and new equipment for the transportation system; duplication of the water-works system.

Building 125-Mile Transmission Line in Northern Ontario

Work has been started on the 125-mile transmission line from the new power plant of the Des Quinze Power Co., a subsidiary company of the Northern Canada Power Co., on the Des Quinze River in Quebec to Porcupine, Ont. The power line is to be built with steel towers and with transformer stations at each end and stepping-down stations at the various mining camps in the Porcupine area which it will serve. It is expected that the construction parties will be able to erect 3 mile of line a day, employing up to 1,000 men on the work. If this is done the transmission line will be completed at about the time that the machinery will be delivered at the new power plant. The estimated cost of the transmission line is \$1,500,000.

The initial installation at the Des Quinze River power plant will be two units of 10,000 hp. each. C. F. Goodall, who built upwards of 1,000 miles of transmission line for the Ontario Hydro-Electric Power Commission, is in charge of the work.

Work Assailed for Removal of A. P. Davis

Civil Service Reform Leader Questions Secretary's Right to Replace Reclamation Director

Authority of Secretary of Interior Work to abolish an office in the classified civil service list and to appoint to that office, by a mere change in title, a man lacking in any civil service status, is seriously questioned in a letter from William Dudley Foulke, president of the National Civil Service Reform League, to Dr. Work. The letter, made public Aug. 27, goes into the details of the summary dismissal of A. P. Davis, as director of the Reclamation Service, and the appointment of D. W. Davis as commissioner.

Mr. Foulke suggests that the change was one of political expediency and not the replacement of an engineer by a banker to effect a business administration in the service. After discussing the comparative qualifications of the two men, Mr. Foulke asks:

"Can you wonder that to many it seems that your statement of Aug. 15 that the problems of water users could be 'best handled by a practical business man,' alludes rather to the business of politics than to any other business, and that there is a fear that the public interest will be sacrificed to the demand for men useful to the party, not only among the farmers and water users, but also in the next convention and campaign?"

"You once stated to me that 'other things being equal, Republicans should be appointed to places under a Republican Administration.' Are you not now extending that principle so as to make it provide that a serviceable Republican politician should be appointed whether other things are equal or not?"

RESIGNATION OR DISMISSAL?

"Was Mr. Davis's resignation voluntary or requested? Was he not informed by you on June 16 that you had decided to give his place to another man, and did you not then request him to send in his resignation to take effect June 30?"

"Did he not, accordingly, write you that in pursuance of your suggestion he so tendered his resignation, and did you not thereupon object to his statement that the resignation had been requested and say that you would prefer that it should appear that it had been initiated by himself and that surely he would not desire to advertise the fact that he had been 'fired'; and did he not answer that he desired the world to know the facts, whatever they were? Did he not afterward write you that he had reconsidered his decision to eliminate those words, concluding that he would thereby be making himself party to a public deception?"

"If your reasons for his removal were wholly for the interest of the service and were not political, why did you wish thus to deceive the public?"

(continued on p. 363)

Private Capital May Develop Ohio River Power

Though Denied Application for Federal Dam Project, Louisville May Yet Control Private Enterprise

Washington Correspondence

The Federal Power Commission has granted a preliminary permit to the Louisville Hydro-Electric Co. to develop power at the proposed government dam at the falls of the Ohio near Louisville and has rejected the application of the municipality of Louisville for similar rights. This action is the result of the recommendation of the engineering staff of the commission and closes a long argument as to who should develop power at this site—Louisville or private capital.

The engineering report points out that this development is of little value unless it has auxiliary power to supplement it and that the city, in order to make it a paying proposition, would have to build an auxiliary steam plant as well as a complete distributing system, or else would have to take over the property of the Louisville Gas & Electric Co. by condemnation proceedings. In either case the amount of money required would exceed the present bonding capacity of the city of Louisville, and would consequently require an act of the state legislature before the bond limit could be increased.

The engineers further point out that the Louisville Gas & Electric Co. has the necessary distributing system and steam auxiliary. Moreover, the proposed power development is feasible only as an adjunct to navigation development on the Ohio River, and as this navigation development must be started within a year, since it is part of the remaining gap to provide 9-ft. navigation in the Ohio from Pittsburgh down, it would be impossible for the city of Louisville to get through the necessary legislation in time to start the development.

Construction Started on Merced River Dam

All bids on the construction of the Exchequer dam on the Merced River for the Merced Irrigation District have been rejected and the work will be done on the day labor plan by the district under the supervision of Thebo & Anderton, construction engineers of San Francisco. Work has already been started on foundation excavation in the expectation of taking advantage of the next low water season in placing the footings. The dam will be 310 ft. high above the river bed, the total height not being definitely known until the foundation exploration is complete, but it will not greatly exceed the height mentioned because good foundation is known to be near the surface at this point. The construction period is expected to occupy about two years.

The construction of this reservoir will necessitate the relocation of about 17 miles of the Yosemite Valley R.R. and estimates are now being made on grading and other work involved in the railroad relocation.

The report still further points out that the city has legal authority to regulate rates and can therefore protect itself, and that whenever it is able and ready to condemn and take over the properties of the Louisville Gas & Electric Co., it can take over this hydro-electric development as well. Therefore, the rejection of the city's application does not deprive the municipality of the right to go into the power business whenever it is ready to do so.

Since the Louisville Gas & Electric Co. did not promptly accept its preliminary permit the Federal Power Commission has advised the mayor of Louisville that it will hold up the execution of the permit until Sept. 6 to afford the municipality an opportunity to present additional arguments in favor of municipal development.

New Tunnel to Be Built in San Francisco

The San Francisco board of supervisors on Aug. 20 approved the construction of the Eureka Valley tunnel, a vehicular and railway tunnel, 1,634 ft. long, near the Twin Peaks tunnel, which will open up a direct route from Golden Gate Park and the Sunset district to Market St. and the Mission district. The bore is estimated to cost \$1,368,107 of which the city has voted to pay 25 per cent, the remainder to be paid by an assessment on benefited property.

A. G. C. Organizes in Denver

A chapter of the Associated General Contractors of America has been effected in Denver Colo. This new concern will be known as the Rocky Mountain branch and it will comprise the states of Colorado, Wyoming and New Mexico. The officers are: Alex Simpson Jr., president; Major W. R. Richards, executive secretary; Maurice Levy, vice-president; Fred C. Dreher, secretary-treasurer. The board of directors: F. J. Kirchhof, C. S. Lambie, Peter Seerie, J. Fred Roberts, J. Everett Young, all of Denver, and Fred Bullen, of Pueblo. Major Richards has had extensive service in railroad, water works and general building construction, and was at one time associated with the J. G. White Engineering Corp., of New York, leaving that concern to enter service during the war.

Headquarters for the Rocky Mountain branch are at the Architects and Builders Exchange building, 1735 Stout Street.

Akron Votes to Transfer Power of City Manager to Mayor

By a majority reported as "exactly 100" in a total vote of "more than 14,000," or "only a small per cent" of those entitled to cast a ballot, the voters of Akron, Ohio, on Aug. 14, adopted a series of charter amendments abolishing the office of "chief administrator" (the local charter designation for city manager) and conferring the duties of the office on the mayor. The charter was adopted Nov. 5, 1918, by a vote of 11,584 to 6,233.

When the charter thus amended went into effect on Jan. 1, 1920, the city council appointed William J. Laub, mayor elect, as city administrator, and the president of the council became mayor. Two years later, after a "bitter fight," a new council displaced Mr. Laub by Homer Campbell. In the September following Mr. Campbell resigned, stating that he was "undesirable to the city political bosses," and P. Tucker was appointed in his place. The salary of the city administrator was \$10,000 a year while Mr. Laub was in office and has been \$7,500 since. The salary of the mayor has been \$3,600 a year but with the transfer of the duties of city administrator to the mayor it will be \$7,000. The chief administrator was appointed by the council. He appointed a civil service commission and most of the department heads.

The population of Akron in 1920 was 208,435, as compared with 152,559 for Dayton and 137,634 for Grand Rapids, Mich., the two ranking cities with city managers. On Jan. 1, 1924, the council-manager plan will go into effect at Cleveland, Ohio, the population of which in 1920 was 796,841.

Don Pedro Reservoir Fills Promptly

THE reservoir behind Don Pedro Dam on the Tuolumne River in California, recently completed in a twenty-two months rush construction program, filled, as did the Hetch-Hetchy reservoir which is farther up the same stream, within a few weeks after closure was

made. The Don Pedro Dam is 282 ft. high and was built jointly by the Turlock and Modesto Irrigation Districts for storage purposes. A comprehensive description of the construction plant was published in *Engineering News-Record* June 1, 1922, p. 896.

Army Engineers Hear Plan For Bridge Over Hudson

Clearance Height and Safety To Navigation Are Principal Topics Discussed

On Aug. 27 a public hearing was held at New York by a board of Army engineers headed by Col. H. S. Newcomer on the project of the North River Bridge Co. for a suspension bridge across the Hudson from 57th St., New York, to the Weehawken heights. The plan submitted by the company provides a main span of 3,240 ft. between centers of towers and side spans of 1,590 ft. on each bank with a clearance height of 150 ft. on a 500-ft. width, 145 ft. on a 1,500-ft. width, and 135 ft. near the towers. The towers are steel structures enclosed within a masonry protecting shell, resting on piers 200 x 400 ft. seated each on 80-ft. cylinders sunk to rock by open dredging. The superstructure comprises two superimposed eyebars chains on either side of the deck, 160 ft. apart, with trussing of verticals and diagonals between the two chains. The deck is 235 ft. wide and has two levels, the upper for highway and the lower for railway traffic; it is carried on stringers extending between steel plate-girder floorbeams 35 ft. deep by 225 ft. long, built with six rectangular openings through the webs, each long enough to pass two tracks of the twelve railway tracks of the lower level.

Col. Newcomer stated that the hearing was concerned only with matters affecting navigation, including clearance height and safety. Span width was not considered as the pier locations are inside the pierhead lines. In addition to many letters supporting the project several were presented in opposition, including two by engineers, R. S. Buck and W. L. Saunders, the former urging that the traffic of the highway deck would congest the streets of New York and that the structure proposed is of unprecedented character.

INTERSTATE TRAFFIC DISCUSSED

Speakers in support of the bridge projects discussed the needs of traffic between New York and New Jersey in various aspects. Opposition discussion centered on the question of clearance height. Col. Newcomer stated that six or seven steamships would require a clearance height of 225 ft. to pass their masts, and some 30 others would require more than the 150 ft. proposed. Representatives of lines operating large vessels claimed that the location at 57th St. would restrict the use of the new piers for maximum ships at 46th St., and that for the purpose of docking at flood tide the bridge should be a clear distance of a mile above the piers unless its clearance height on the full width were greatly increased. They admitted on question, however, that masts and funnels could be arranged to be lowered when necessary. The 135-ft. precedent set by the permits for the Brooklyn bridge and the new Philadelphia bridge was declared inadequate and hampering by members of the board. Questions of the board were directed repeatedly to the point whether tunnels would meet the traffic needs of the two sides of the river, with generally negative response.

For New York City R. F. Keller presented the views of the Dock Department and A. S. Tuttle, chief engineer, spoke for the Board of Estimate. Plans

Consulting Engineering Organizations Affiliate

George B. Nichols, consulting engineer, 300 Madison Ave., New York City, and The Terrell Croft Engineering Co., of which Terrell Croft is directing engineer, of 6600 Delmar Boulevard, University City, St. Louis, Missouri, have effected an affiliation whereby the experience and resources of each organization will be available to the clients of the other. Nichols will act as the principal for projects east of Illinois, whereas the Croft organization will so act for projects west of that state. The combination will, as have its components in the past, specialize in mechanical and electrical engineering for power and industrial plants, institutions and buildings.

Work Assailed for Removal of A. P. Davis

(Concluded from p. 361)

"You say that no diminished construction program is anticipated, but rather an increased and accelerated construction, and that the same chief engineer now is at the head of the work. But if these vast projects are still before you, ought they not still to be under the direction of the experienced man who had begun them—a man who was then offered and is now earning in private employment far greater compensation than that received from a Government which he was patriotically serving to his own pecuniary loss?"

"You say you offered him an appointment as consulting engineer. Was not this offer made on condition that he would omit the statement that his resignation as director was requested? And did you not warn him of the consequences to himself if he refused to omit that statement? Why did you do this? Did he not request of you a written statement of the reasons for his removal, and did you not answer that he was not entitled to such a statement under the law?"

"You say advice to the farmers was needed regarding the subdivision of large landholding, getting more settlers, securing industrial enterprises, more intensive farming and co-operation in handling and marketing products by men trained along these lines. Is not such service now being rendered by men trained along these lines in the employment of the Department of Agriculture?"

"If you were looking for business qualifications, did you appoint a man who had been successful in business? Was the bank of which Governor Davis was the organizer and president markedly successful? Was it not rather to politics that his principal activities have been devoted? Had he not been a candidate for other Federal appointments?"

are under way for new large-size piers at 50th St., Mr. Keller stated, and the northward extension of pier construction is likely to progress farther. The problems of street congestion and proper distribution of the bridge traffic, said Mr. Tuttle, will be considered by the city at a later stage, when detail plans are presented by the company.

It is expected that the decision of the War Department on the application for approval of the plans will not be rendered for several weeks.

Pinchot Makes Last Effort To Avert Coal Strike

Unless Compromise Plan Is Adopted, Miners in Anthracite Fields Will Strike Sept. 1.

After having failed to come to any agreement either in the extended Atlantic City conference or in the subsequent conference in New York City attended by members of the U. S. Coal Commission, anthracite operators and miners are still deadlocked on vital controversial issues: the wage schedule that is to replace that which expires Aug. 31, and the checkoff. Unless speedy and effective measures are adopted the country will face a stoppage of all anthracite mining Sept. 1.

Meanwhile, Governor Pinchot, of Pennsylvania, called in as official referee, has been holding for the past three days secret and separate conferences with both miners and operators in the endeavor to get them to agree to some compromise plan which will avert a strike. At the same time he has been employing his own state-finding commission presided over by Prof. Clyde C. King, former head of the department of economics of the University of Pennsylvania and now state secretary of that state composed of industrial and economic researchers and writers, to gather data on the economic phases of coal digging and distribution. Upon such data will his decision be based.

Only rumors of the compromise plan in Gov. Pinchot's mind have been heard, the details of the plan having remained secret, but at the time of going to press the proposal is about to be given both contestants. However, it is thought that Gov. Pinchot may suggest an increase in miners' pay of 5 per cent or better, and allow the operators to reject the miners' insistence that they be granted the checkoff.

In a statement issued Aug. 30 the U. S. Coal Commission asserted:

"Should a stoppage of mining occur on Sept. 1, it will accentuate the already panic demand for anthracite and unless the buyer and the retailer representing him learn from past experience, unscrupulous wholesalers will have another opportunity to repeat their speculative activities of last fall and winter on any anthracite coal that may be on the market after Sept. 1, as well as following the resumption of mining. In the absence of any definite regulatory powers over either mine prices or wholesalers margins on the part of the state and federal authorities, the extent of such activities, and the amount of premium added by wholesalers will depend largely upon the willingness of the retailer and the consuming public to pay the prices demanded."

Tentative Value Given C. & N. Ry.

A tentative value of \$485,334,029 has been placed on the property of the Chicago & Northwestern Ry. by the Interstate Commerce Commission as of June 30, 1917. Since that date the railroad company has expended \$57,820,981 on road and equipment, which brings the total value of the railroad and equipment up to \$543,155,010. The company's bonded debt on Dec. 31 last was \$287,906,700, and its preferred stock \$22,395,120, which leaves a balance of \$232,853,190 or about \$150 a share on the common stock, of which \$145,156,344 is issued.

Random Lines

Add to Definitions

Liquidating Engineers—Second-hand machinery agents (*Engineering News-Record* advertising pages).

Kitchen Engineering—Free course conducted by domestic science experts from Antioch College as part of sales campaign for kitchen cabinets in a Dayton department store.

Packing Engineering—Department of trade journal "The Barrel and Box" devoted to methods of boxing and crating goods.

Caterpillar Engineers—Gentlemen engaged in driving tractors in clearing land. Reported in the *Girard, Cal., News*. Probably not related to "mosquito engineers" previously noted.

Vocational Engineer—"Character analyst" in Baltimore who picks "right man for right job."

Hot Dog Engineer—The last word in engineering nomenclature. Discovered by W. G. R. as a concessionaire in Fairmount Park in Philadelphia. One member of the profession who believes in advertising himself, ethics or no ethics. See accompanying illustration.

Sir—With respect to the editorial "An Explanation That Does Not Explain," dealing with the removal of Arthur P. Davis, it is evident that a weak defense of an indefensible action calls for work with a capital W.

A. W. W.

Maybe They Meant Sand-Chucks

In a book review published in an architectural contemporary appears the following: "It seems strange that the writers of books on foundations neglect to have some practical sections written by experienced digger foremen and superintendents, commonly known as 'ground hogs.'" Doubtless this accounts for the large numbers of men who may be seen each Feb. 2 emerging from excavations all over the land and hunting so diligently for their shadows.

Mud-Laden Water at Omaha Causes Water-Works Trouble

Erosion of a mud bank on the shore of the Missouri River above the intake of the water-works supplying Omaha, Neb., and vicinity, combined with a large accumulation of sediment in the settling reservoirs, both due to high water in the river, gave rise to some alarming press dispatches sent over the country last week. The following details of just what happened and how the emergency was met were sent to *Engineering News-Record* at its request by R. B. Howell, general manager of the Metropolitan Utilities District, under date of August 24:

"The Metropolitan Utilities District has been installing a 50-m.g.d. filtration plant in connection with its sedimentation basins and has also been putting in two additional pumps at the Florence station, increasing the pumping capacity by about two-thirds. This work, which is nearing completion, has necessitated certain pipe connection changes that have interfered with the regular washing of the sedimentation basin. As a consequence, the capacity of the basins for clearing the water was reduced. In this crippled condition the basins were called upon to cope with the present high stage of the river and also with the effect of the erosion of a mud bank on the west side not far above the intake. The resulting quantities of silt introduced into the basins proved the last straw, and the clarifying process broke down. There was but one thing to do in the emergency, and that was to wash the basins. This work has been carried to the point where it is possible to operate the filter plant at a rate high enough to furnish the entire consumption of the city. Now that the turbid water in the mains is being displaced by filtered water, the conditions (as to the quality of the supply) are becoming normal. It is anticipated that all consumers will be receiving an excellent quality of water by Aug. 26."

Illinois Central R.R. Will Start New Line Immediately

Construction work on the new line of the Illinois Central from Edgewood, Ill., to Fulton, Ky., will be started immediately according to the announcement of the senior vice-president of that railroad. The new line will start from Edgewood, Ill., a point about midway between St. Louis and Terre Haute, and will run due south through Illinois to some point on the Ohio River near Metropolis, where it will cross the Ohio and continue south across Kentucky to connect again with the Illinois Central system at Fulton, on the Kentucky-Tennessee border.

This new line has met with considerable opposition from certain interests in Illinois, particularly from Cairo and the surrounding territory, as that territory fears that by the construction of this second line it will no longer be on the main line of the Illinois Central. The Interstate Commerce Commission after hearing all the arguments has granted the Illinois Central permission to build the line. It will have a total length of 166 miles, will shorten the route to New Orleans by 21 miles, and will reduce the grade against coal traffic considerably. The estimated cost is \$16,500,000.

European Design Prize to Honor American Engineer

A Lindenthal prize for artistic design has been instituted by the Verein Deutschösterreichischer Ingenieure. It is to be awarded each year to the best design of architectural and engineering character presented at the Behrens school of the Vienna Academy of Arts. The initial award has just been made for the design of a hydro-electric powerhouse. The prize is named after Gustav Lindenthal, engineer of the Hell Gate Arch and the proposed Hudson River suspension bridge, who was born in Austria.

Bankers Plan to Finance New York Port Development

Representatives of sixteen large financial institutions in New York City have held an informal conference with the New York Port Authority and have proposed a scheme of financing the plans for developing the port according to the comprehensive plans of the Port Authority. It is estimated that the plan will require from \$100,000,000 to \$200,000,000 before it is completed, but this sum will only be required in small amounts as the various units in the plan are developed. The money would be raised by bond issues secured by the actual property of the Port Authority and guaranteed by the states of New York and New Jersey. This plan is very similar to that in use in European ports, such as the Port of London, and provides a very attractive form of investment.

Steps for Large Sewage-Works for Part of New York City

Preliminary steps to acquire the right to use for sewage disposal land on Wards Island northeast of the New York Connecting Ry. have been recommended to the New York Board of Estimate and Apportionment by Arthur S. Tuttle, chief engineer, in accordance with a report of Kenneth Allen, sanitary engineer of the board. The board has concurred in the recommendation. The plan is to get permission from the Commissioner of the Land Office for the transfer of the lease of some fifty acres of land from the State of New York to the City of New York.

In his report on this subject (*New York City Record*, Aug. 15, p. 5386), Mr. Allen in discussing the degree and kind of treatment required, stated:

"The extent of treatment depends upon the steps taken to clean up the rest of the East and Harlem Rivers. The least degree of treatment to be considered would be sedimentation in tanks, but it is probable that some more thorough method, such as that known as the activated sludge process, will be found necessary. With the latest developments in this process 10 m.g.d. may be treated daily on one acre of ground, so that the 202, or at most 232, m.g.d. to be expected in 1960, would require not over 24 acres or about half the area now suggested."

The sewage to be treated on the site in question would come from adjacent areas in Manhattan, The Bronx and possibly Queens. This project is part of a tentative plan to treat as much sewage as local conditions demand.

Engineering Societies

Calendar

Annual Meetings

NEW ENGLAND WATER WORKS ASSOCIATION, Boston, Mass.; Annual Convention, Burlington, Vt., Sept. 18-21, 1923.

INTERNATIONAL ASSOCIATION OF STREET SANITATION OFFICIALS, Chicago, Ill.; Annual Conference, Chicago, Sept. 27-28, 1923.

AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 8-11.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 17-20.

AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga.; Nov. 12 to 16.

CITY MANAGERS ASSOCIATION, Lawrence, Kansas; Annual Meeting, Washington, D. C., Nov. 13-15.

The San Francisco Section, Am. Soc. C. E. held an excursion and barbecue on, Saturday afternoon and evening Aug. 11, at Sunol, Calif., as guests of the Spring Valley Water Co. About eighty members and guests made the trip by automobile; inspection was made of work on the Calaveras Dam and on the new reinforced-concrete aqueduct two miles long which is now under construction in Niles Canyon. The barbecue dinner was served near the Sunol water temple, after which there was a short talk by George A. Elliott, chief engineer of the company, on "The Immediate Development and Delivery of an Additional Water Supply for San Francisco Amounting to 24 Million Gallons Daily."

The Engineering Institute of Canada has organized a branch at Kenogami in the Saguenay district, with an initial membership of 51. This branch was inaugurated through the enterprise of the Montreal branch of the institute. Officers at Kenogami were elected as follows: chairman, W. Mitchell; secretary-treasurer, H. B. Pelletier.

Personal Notes

ROBERT GILMOUR, superintendent of Montreal terminal stations of the Canadian National Rys., has been appointed assistant to the general superintendent, Canadian Nationals Rys., office at Montreal.

BRIAN R. PERRY, formerly engineer with P. Lyall & Sons Construction Co., Montreal, has joined the staff of the McKinnon Steel Co., Ltd., of Sherbrooke, P. Q., with offices at Montreal. Mr. Perry is a graduate of McGill University.

U. G. I. CONTRACTING Co. of Philadelphia, a concern engaged in contracting, construction and engineering has filed a copy of its certificate of incor-

poration with the Secretary of State at Albany, New York, in order to enable it to do business in this state, through A. D. Dudley of 421 South Warren St., Syracuse, N. Y., as its agent.

H. W. GREEN has resigned as sanitary engineer on anti-malaria work with the International Health Board of the Rockefeller Foundation to enter service of the Cleveland Health Council as director of the Bureau of Statistics and Research for the Cuyahoga County Public Health Association. With the Rockefeller Foundation Mr. Green had charge of a demonstration and investigation project in Porto Rico.

PROF. W. K. HATT will resume his duties as professor of civil engineering at Purdue University, Lafayette, Ind., having served two years on the Advisory Board on Highway Research of the National Research Council. He will continue to direct the affairs of the Advisory Board for the present.

R. W. HEBARD & Co., Inc. have been employed by the city of Limon, principal Atlantic port of the Republic of Costa Rica, to prepare plans for general sanitation of that city.

JAMES E. MILLER, of Chicago, has been appointed trade commissioner of the Department of Commerce at Calcutta, India. Mr. Miller was formerly a consulting engineer with the General Engineering and Management Corp. of New York City, and prior to that was engaged with the Westinghouse Electric & Manufacturing Co. in engineering construction and sales in the United States, Canada, England, France, Russia and South America.

ABRAHAM LEVIN announces the organization of the Technical Service & Engineering Co., himself as manager, in Huntington Park, Calif., for the practice of civil and industrial engineering, especially the designing of buildings for industrial plants. Mr. Levin was formerly connected with the Rider-Connolly Manufacturing Co. of Pittsburgh, Pa., and the Virginia Bridge & Iron Co., Roanoke, Va.

FRANK T. MILLER, Greensboro, N. C., has been appointed chief engineer of the proposed Appalachian & Western North Carolina R.R., which is being sponsored by the state.

W. R. WORLEY, formerly an insurance man, of The Dalles, Ore., has been appointed city manager of Warrenton, Ore., to succeed Mrs. R. E. Barrett, who has resigned on account of ill health.

FREDERICK WILLIAMS, civil engineer and surveyor, formerly assistant engineer of the New Jersey Board of Commerce and Navigation, announces the opening of an office at 336 Main St., East Orange, N. J., for general practice.

CHARLES W. MCKAY, former president and general manager of McKay & Sherman, and more recently head of C. W. McKay and Associates, valuation engineers, has been made manager of the valuation division of Roberts-Pettijohn-Wood Corp., engineers and appraisers, of Chicago.

WILLIAM H. FLAHERTY, formerly located with the Gulf Wrecking Co. at Mobile, Ala., is now a consulting engineer and contractor with office at 44 Whitehall St., New York City.

J. C. MANLEY for some years city engineer of Tacoma, Wash., has resigned, effective Sept. 1, on account of ill health.

J. ALBERT HOLMES, consulting engineer, Boston, Mass., has been selected to make an investigation of and report on flood conditions at Chickasha, Okla., and as consulting engineer on the design and construction of an earth dam at Asheville, N. C.

MCCALL-MOORE ENGINEERING Co., Waco, Texas, a partnership which has existed since 1912, will be dissolved Sept. 1, 1923, and each of the partners will remain in Waco and conduct a business along the same line. Mr. McCall under the firm name of the McCall Engineering Co., and Mr. Moore under the firm name of Bart Moore Construction Co.

HARTIGAN-PROUDFOOT Co. has been incorporated to do a general contracting and construction work at East Chicago, Illinois. Alfred G. Proudfoot, Augustus F. Hartigan and Walter E. Kasten are directors of the company.

RICHARD W. SCHMIDT, formerly a field engineer with the Roxana Petroleum Co., has been made assistant civil engineer in the sewer department of the St. Louis, Mo., board of public service.

WALTER H. FRICK, formerly architect with the West Penn Power Co., has become an assistant civil engineer with the Pressed Steel Car Co., Pittsburgh, Pa.

PROF. L. S. SMITH, professor of engineering at the University of Wisconsin, Madison, has been engaged as city planner for the city of Waukesha, Wis.

HARRISON BROBERG has resigned from the Kansas Highway Commission and has accepted a position as highway engineer with the U. S. Bureau of Public Roads in construction work in the Phoenix, Arizona, district.

GEORGE A. CRANE has been made chief estimator for the Aberthaw Co. in its main office at Boston. Mr. Crane was for five years manager of the Detroit and Montreal offices of the George A. Fuller Co.

GEORGE F. RUSSELL, superintendent of public utilities, Seattle, Wash., has been appointed superintendent of the water department, to fill the vacancy caused by the death of L. B. Youngs.

CLIFFORD A. BETTS, resident engineer on transmountain division surveys for the Denver Municipal Water Commission, has been made office engineer for the Moffat Tunnel Commission, Denver.

CLARENCE F. POST has been named purchasing agent of the Western Pacific R.R., succeeding the late William T. Jacobs, whose assistant he was. Mr. Post has been with the Western Pacific since 1916. He went to the Pacific Coast seventeen years ago as a representative of the St. Paul and Tacoma Lumber Co., and later was with the Grand Trunk Pacific R.R. at Prince Rupert, Canada.

GEORGE PERRINE, construction engineer for Rodgers & Hagerty, Inc., general contractors, New York City, is

now engaged on the construction of the New York approach of the vehicular tunnel, for which this firm has the contract. Mr. Perrine's engineering estimating and construction experience includes elevated railway and subway work in Baltimore, Washington and New York City, and charge of construction of the Cathedral of St. John the Divine in New York City.

E. J. TERRILL has been appointed division engineer of the Southwest division of the Kansas State Highway Commission with headquarters at Dodge City, Kan. Mr. Terrill was formerly resident engineer on federal-aid projects in Montgomery County.

JAMES E. BARLOW, city manager of New London, Conn., since Nov. 1, 1921, has resigned. Lack of support in the enforcement of the liquor laws is reported to be the cause of the resignation. Mr. Barlow was principal assistant city engineer of Cincinnati under H. M. Waite and went to Dayton, Ohio, early in 1914, to become director of public service under Mr. Waite as city manager. When Mr. Waite resigned in 1918 to enter the army as lieutenant-colonel, Mr. Barlow became city manager of Dayton.

C. R. RANKIN, assistant city engineer of San Francisco, who has been resident engineer on the recently completed O'Shaughnessy Dam on the Hetch Hetchy project, has been put in charge, for the city, of the construction of the 24 m.g.d. conduit that will be used for the present by the Spring Valley Water Co. to bring an additional water supply into San Francisco.

ROBERT S. SUMNER, civil engineer, with offices in the United States National Bank Building, Denver, has been appointed a member of the Denver Water Commission, relieving FINLAY L. MACFARLAND. Mr. Sumner is a member of the American Society of Civil Engineers. PETER SERIE, local contractor, has also been appointed a member of the commission, filling the vacancy caused by the death of JOHN C. SKINNER.

CHARLES A. HOWLAND has been appointed on the technical staff of the Philadelphia Bureau of Municipal Research to fill the position left vacant by the resignation of J. W. Follin. Since 1920 Mr. Howland has been estimating and construction engineer on water supply, sewerage and paving improvements for the Benham Engineering Co., Kansas City. Previous to that, since graduation from Cornell University, he was inspection engineer and then assistant sanitary engineer for the New York State Department of Health, this service, however, having been interrupted by service in France during the war with the 102nd Engineers.

LIEUT.-COL. FRANCIS A. POPE, Corps of Engineers, recently arrived at San Francisco from the Philippines, has been ordered to Norfolk, Va., for duty. Lieut.-Col. Pope was, during the war, first in command of the 301st Engineers and division engineer of the 76th Division, and in 1918 in command of the 315th Engineers and division engineer of the 90th Division. Since the war he has served at Duluth on river and harbor improvements and in the Philippines.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

To Draw for Exhibit Space at Good Roads Show Soon

Announcement will soon be made of the date for drawings for exhibit space at the annual Good Roads Show, to be held in the Coliseum, Chicago, Jan. 14-19, in connection with the convention of the American Road Builders' Association. As announced in this journal Aug. 16, p. 284, Charles M. Upham, state highway engineer of North Carolina, has been appointed manager of the convention and show and will be granted a leave of absence by the State Highway Commission of North Carolina in order to devote his time to completing arrangements for the Chicago convention and exhibit of road-building equipment and materials. Mr. Upham will open an office in Chicago well in advance of the convention date. Mr. Upham will report directly to the executive committee of the American Road Builders' Association. With the approval of that committee he will appoint several committees to handle various features of the two big events of the year in the highway industry.

President Frank Page has received from S. F. Beatty, president of the Highway Industries Exhibitors' Association assurances of that body's co-operation in making the 1924 Good Roads Show a success.

All inquiries regarding the convention and show should be addressed to the home office of the American Road Builders' Association at 37 West 39th St., New York City, until the announcement of the location of the temporary Chicago office has been made.

Barnes Cites Production Records of American Industry

Julius H. Barnes, president of the Chamber of Commerce of the United States, in an address Aug. 22 before the National Association of Insurance Agents, cited ten production records that have been established in industry during the last few months. They are: largest pig iron production; largest cotton consumption; largest steel ingot production; largest crude oil production; largest automobile and truck production; largest residential construction; largest production of locomotives; largest volume of mail-order sales; largest volume of retail sales; largest volume of railroad car loadings.

Mr. Barnes also made several significant comparisons of changes that have taken place in the United States since the pre-war year of 1913. The more important comparisons are:

"The population of the United States has increased 14,000,000 people, with their enlarged requirements.

"The annual national income has increased from 34 billion, to 50 billion dollars.

"The aggregate savings deposits have increased from 6 billion to 14 billion dollars.

"The deposits in national banks have increased from 6 billion to 17 billion."

Ten Thousandth Mixer Order Shipped by Koehring Co.

Mixer order No. 10,000, a 14-E paver, was completed and shipped Aug. 1 by the Koehring Co., Milwaukee, to the Julian C. Field Co. in Texas. The 10,000 concrete mixers have been sold by the company during the period of 16 years that it has been engaged in the production of this type of construction equipment.

Early Shipments Urged to Prevent Freight Car Shortage

Intimation of a threatened freight car shortage this fall has been given by the Public Relations section of the American Railway Association in an advisory circular just issued to trade organizations urging manufacturers to increase their efforts to expedite the movement of freight before the usual heavier shipments of the fall begin.

"The fact that there is no appreciable car shortage today should not serve as a basis for lessening the efforts to move as much as possible before the fall period," says the railway association's warning to shippers and consumers. "The volume of traffic now being handled is far in excess of that tonnage which the Car Service Division originally anticipated would be offered the railroads. To avoid car shortage this fall shippers and consumers must continue and augment during the next thirty days their efforts to level off the peak of shipments during the coming fall."

HEAVY CAR LOADINGS

The American Railway Association reports that the railroads are now moving the greatest volume of freight in the history of the country. This is being done practically without car shortage, due to increased efficiency of operations, installation of new and better facilities, active co-operation of industry and agriculture in promoting the most efficient use of transportation facilities and in moving a substantial tonnage in anticipation of future requirements.

"From the best economic analysis of business conditions which we are able to obtain," says the railway association, "the measure of the large railroad tonnage being offered is due not only to a general increase in business activity, but also to the efforts which have been put forth in some industries to stock in advance in anticipation of future needs. Notwithstanding this progress, inventories throughout the country are not extra large, and all indications seem to point to continued business activity and heavy car loadings.

"The railroads are vitally interested in discharging their responsibilities this year in the most adequate manner possible, but to accomplish this end, and minimize car shortage during the peak fall movement, nothing should be left undone at this time to move the tonnages of those commodities which can be properly stocked by consumers during the next thirty days to meet their

fall and winter requirements. This is especially true of coal, lumber, sand, gravel and other building materials, and those commodities the need of which has already been set out in definite future programs."

Paving Brick Production in July

Steady production of vitrified paving brick during July is reported by the National Paving Brick Manufacturers Association, Cleveland. The July statistical report covering 68 per cent of the normal tonnage capacity of the industry, shows production 30,529,000 and shipments 27,092,000 brick as compared with a June production of 31,105,000 and June shipments of 27,251,000. Stocks on hand at the end of July were 78,835,000 brick, as against 75,398,000 at the beginning of the month.

July shipments were made into thirty states and Canada, with Ohio leading in consumption followed by Illinois, Texas, Iowa and Pennsylvania in the order named.

Automobile Production

The Department of Commerce announces July production of automobiles, based on figures received by the Bureau of the Census and covering approximately 90 passenger-car and 80 truck manufacturers each month as follows:

	AUTOMOBILE PRODUCTION (Number of Machines)			
	Passenger Cars	Trucks	1922	1922
January.....	223,706	81,693	19,398	9,416
February.....	174,650	109,171	21,817	13,195
March.....	319,638	152,959	34,681	19,761
April.....	344,474	197,216	37,527	22,342
May.....	350,180	232,431	43,013	23,788
June.....	*337,143	263,027	40,616	25,984
July.....	297,104	224,770	29,998	21,837

* Revised.

American Designs Copied Abroad

That American manufacturers need proper protection in foreign countries for their designs, patents, trademarks and copyrights is emphasized by the Department of Commerce in the following statement:

The superiority of American machinery is generally recognized in foreign countries, and in a great many instances designs have been copied and the business so handled as to work to the great disadvantage of American manufacturers. In some instances foreign interests send to this country inquiries for equipment and stipulate that detailed working drawings must be furnished with proposals—endeavoring, through one subterfuge or another, to secure full particulars of the working details. Very often it develops that this is done to facilitate their own work in producing copies.

The matter is referred to because the Bureau of Foreign and Domestic Commerce has been in receipt of further reports showing how foreign manufacturers of machinery have succeeded in securing detailed drawings enabling them to produce copies of American types of machinery. It is therefore suggested that, when foreign inquiries call for the furnishing of detailed drawings, the matter be taken up with the Bureau of Foreign and Domestic Commerce, Washington, D. C., as there is a fair probability that, through co-operation between this government bureau and the manufacturers, a way will be found to meet the requirements of the situation, and at the same time overcome the risk of furnishing working drawings to a foreign competitor.

Discuss Asphalt Paving Practice at Denver Conference

By ROY J. RANDALL

Office Engineer, State Highway Department, Denver, Colo.

DISCUSSION at a conference on asphalt paving held at Denver, Colo., Aug. 21 and 22, and participated in by highway engineers, contractors, and producers of asphalt, was notable in the diverse opinion expressed. Many of the points brought out in certain papers were contradicted in others, the effect being to leave one at a loss as to what was considered correct procedure.

A state highway engineer said that the use of asphalt was particularly suited for paving in his state on account of the wide variety of mineral aggregates to be found locally. While these aggregates differ considerably in composition, size and quality, they can all be used with asphalt for paving with satisfactory results by changing the specifications for the mix to suit each locality. He called attention to the fact that few of these local materials, which were found to be suitable for asphalt paving, were suitable for concrete.

In contrast with this paper, another speaker made the statement that the largest single cause of failure in asphalt paving was due to unsuitable mineral aggregates. While the last paper did not entirely disagree with the first one, it emphasized the necessity of using no local material for asphalt paving unless tests had shown that material to be adequate for first-class work.

ALLOWABLE VEHICLE LOADS

Another point upon which there seemed to be a wide diversity of opinion was the allowable loads on highway vehicular traffic. One speaker asserted that no limit should be placed on any load on highways, and that engineers could design roadways to accommodate any load, and accomplish this result with comparative ease. Later at the conference another speaker vehemently attacked the position of engineers who were designing pavements and structures for loads of from 15 to 20 tons. He stated that, in his opinion, a load from 10 to 12 tons should be the maximum allowed on any public highway.

A large number of the speakers materially digressed from the subjects assigned to them and wandered into the field of comparison between the rigid and semi-rigid types of pavement. Some rather broad statements were made concerning the "sinful waste of public funds" entailed by those officials who continue to pave with concrete.

The writer somewhat regrets that more time at the conference was not employed in the discussions of the speakers concerning the weak points in asphalt pavement—how they might be corrected, and points which should be carefully watched in laying asphalt pavement. However, many valuable examples of special construction work were given during the progress of the conference, such as the laying of asphalt pavement between street-railway tracks and on bridge floors.

Among the speakers were J. E. Pennybacker, of the Asphalt Association, Roy M. Green, Western Laboratories, E. P. Allen, Standard Oil Co. of Indiana, C. P. Jensen, Fresno, Calif., J. A. Griffin, Los Angeles and S. H. Diggs, Midwest Oil Co.

Business Notes

H. D. CONKEY & Co., Mendota, Ill., manufacturers of cranes and industrial cars, announce the appointment of the Florandin Equipment Co. as New York sales agents. The latter organization, in addition to handling the distribution of Conco cranes in the New York district, is agent for the hoists manufactured by American Engineering Co.

LINK-BELT Co., Chicago, announces a reduction in the price of its Cub portable belt loader from \$700 to \$550. The machine is equipped with a two or three phase, 60-cycle motor, and fitted with raising or lowering mechanism.

DR. THOMAS ADDISON has retired at his own request as Pacific Coast manager of the General Electric Co. and will be succeeded by J. A. Cranston, formerly Northwestern manager. Dr. Addison has been with the company for 33 years, and has held his present position since 1892. He was born in Courtland, Mich., and was graduated from Bellevue Medical College with the class of 1877. In 1885 he forsook his profession of medicine to take employment with the United States Electrical Co. of Chicago, and in 1888 accepted a position as apparatus salesman with the Thomson-Houston Co. at that city. When the western branch of the company was reorganized in 1890 he was selected to go to San Francisco as local manager. Two years later he became Pacific Coast manager of the General Electric Co.

Equipment and Materials

Heavy Oil Engine Designed for Low Operating Costs

Economical operation, due to the use of low-priced fuels of the semi-Diesel type, kerosene or Pacific Coast distillate, together with operating flexibility, lightness of weight and bulk comparable with a gasoline engine, are among the advantages claimed by the Automatic Machine Co., Bridgeport, Conn., for its four-cylinder heavy-oil engine manu-

factured in sizes with a power range from 19 to 150 hp. This motor, its manufacturer claims, is particularly adapted to the operation of heavy construction equipment, such as steam shovels, locomotive cranes, hoists and other material-handling plant or may be employed as a separate portable power plant for the operation of electric generators, conveyors and other types of machinery.

The feature of the equipment is its light weight compared with other types of oil engine, amounting to about 50 lb. per horsepower. As to fuel consumption, tests indicate that about $\frac{1}{2}$ lb. of oil is required per horsepower-hour. The engine operates at from 450 to 525 r.p.m., the same speed as the company's heavy-duty gasoline engine. The motor is equipped with a standard electric starter and a gear pump insures the constant flow of lubricating oil to all internal working parts. For ignition a jump spark is used instead of hot bulbs. For operation there is a moderate compression, which, however, is high enough to insure good fuel economy and at the same time low enough to prevent frequent repairs to the engine. A ball type of governor, driven by a pair of spiral gears, automatically adjusts the power to the load. The cylinders are water-cooled. Through the entire range from no load to full load the speed is controlled by the movement of the throttle, there being no other valves or levers to be regulated. With the exception of its height the dimensions of the heavy-oil engine are the same as the company's gasoline engine so that the two types of machines are interchangeable on the same foundation.

Theft-Proof Electric Bulb

To prevent theft of electric bulbs on construction work and in industrial buildings, hotels and schools, a special design of lamp which fits any standard socket has been developed and placed on the market by Lester Kulp,

143 West Austin Ave., Chicago. The main parts of the bulb, which is without guards, locks, keys or springs, are shown in the accompanying illustration. One contact is at the top, just as in an ordinary lamp, and the other through a brass ring fastened at the bottom of a porcelain plug. This plug has a groove which is filled with plaster of paris, lightly holding the brass shell in place. After the lamp is screwed into the socket an extra turn breaks the plaster of paris so that the lamp can turn freely in the shell and at the same time maintain electrical contact. The shell, however, cannot be turned in the socket. The shell is spun over the ring and screws up so close to the socket that fingers or tools cannot grasp it. The bulbs are made in standard sizes and can be removed for replacement when burned out.

An All-Year-Round Explosive

A new non-freezing explosive named "Ammite" has been announced by the Atlas Powder Co., Wilmington, Delaware. In addition to its non-freezing properties the manufacturers claim for it all the advantages of dynamite in strength, water resistance, sensitiveness and stability. The explosive is made in six grades, 75, 60, 50, 40, 35 and 30 percent. These are claimed to be sufficient to meet practically every requirement of blasting in mines, quarries, clay pits or construction work, either above or below ground.

Wheeled Scraper and Leveler Built in Three Sizes

Designed for tractor operation, the Hanford wheeled scraper and leveler is being built in three sizes, 1, 2, and 4 cu.yd., by the Yuba Products Co., San

Francisco. The bowl is mounted on an axle carrying two wheels in such a way that when moving into position or traveling it does not touch the ground, but when dropped into the loading position by the movement of a lever only the forward $\frac{1}{2}$ in. of the blade is in contact with the earth, thus eliminating drag and reducing the amount of power required for hauling. A lever release provides for dumping, and during this operation the bowl swings into a vertical position and rolls upward in trunnions placed on either side. Dumping is controlled by a check chain on the bowl which may be set at any desired length to provide for spreading the dirt or dumping in one pile. Power from the tractor accomplishes the dumping operation.

The smallest sized scraper, with a bowl 5 ft. wide, is a one-man outfit in which the levers are handled from the driver's seat on the tractor. The other two sizes, with 6-ft. and 7-ft. scrapers, require two operators, one driving the tractor and the other on a platform behind the scraper controlling the filling and dumping of the bowl.

New $\frac{3}{4}$ -Yd. Shovel Has Rope Thrust

A new $\frac{3}{4}$ -yd. gasoline rope-thrust revolving shovel, known as the 20-B and embodying the same features as the company's 30-B machine which has been on the market for the past year, has just been announced by the Bucyrus Co., South Milwaukee, Wis. The feature of this machine is the patented rope-thrust arrangement which not only does away with the necessity of en-

gines, gears, clutches, chains or complicated shafting on the boom, but at the same time gives the shovel a drive behind the thrust which is claimed to be more powerful than it is possible to obtain with a steam shovel of the same size, since the whole power of the main engine is behind it.

The shovel is driven by a single, slow-speed gasoline engine. The mo-

tions of the dipper handle are controlled by a small drum on a shaft under the boom, which shaft has keyed to it pinions for engaging with the racks on the handle. The drum is turned either way by two ropes wound around this drum in opposite directions, both ropes leading to drums in the main machinery.

This shovel may also be had with high lift or extra high lift booms, or with dragline, clamshell excavator or crane attachments. The control, according to the manufacturer, is exceedingly simple, and the machinery is arranged with convenience of the operator in mind. Whatever clutches are necessary are sufficiently large to obviate the danger of burning. The caterpillars and frame in general are the same as on the 20-B steam machine.

Publications from the Construction Industry

Test Road Results—PORTLAND CEMENT ASSOCIATION has published a 16-p. pamphlet consisting largely of pictures, with explanatory text, of the results of the traffic tests conducted by the Illinois State Highway Department on the Bates experimental road.

Cold Patch—TEXAS CO., New York, is distributing a 24-p. pocket-size booklet on the use of Texaco cold patch for repairing roads and streets. The text gives the proper proportion of stone and asphalt to be used and describes the preparation of the worn area of the pavement, the mixing and curing of the repair material and the construction of the patch.

Track Drainage—W. S. DICKEY CLAY MFG. CO., Kansas City, Mo., in a 59-p. illustrated pamphlet, sets forth in detail the uses of vitrified clay products for the drainage of railway track. A number of typical installation photographs are shown and there are drawings showing drainage details for a variety of special conditions.

Air Filters—MIDWEST AIR FILTERS, INC., New York, have just published a 49-p. illustrated pamphlet entitled "Dust Problems and Their Solution," showing the application of air filtration to a variety of industrial uses. The filters are essentially shallow steel boxes with perforated sheet metal covers and are filled with filter materials covered with a thin film of viscous fluid. Among the uses suggested for the air filter are in connection with heating and ventilating installations, cleansing air for use in sewage works of the activated sludge type, food and food product plants, paint shops, paper mills, textile mills, hotels and restaurants.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

July Industrial Movements Shown by Government Figures

The Department of Commerce announces the following figures covering industrial and commercial movements in July:

IRON AND STEEL

Pig-iron production in July totaled 3,680,000 tons as against 3,668,000 tons in June and 2,405,000 tons in July a year ago.

Steel-ingot production, allowing for companies not reporting, amounted to 3,516,000 tons as compared with 3,749,000 tons in June and 2,953,000 tons in July, 1922.

Unfilled steel orders at the end of July amounted to 5,911,000 tons as compared with 6,386,000 at the end of the preceding month and 5,776,000 tons on July 31, 1922. Prices of iron and steel declined during the month.

Locomotive shipments by the principal manufacturers amounted to 239 as against 232 in June and 128 in July, 1922. Unfilled orders on the books of these manufacturers on July 31 called for the delivery of 1,738 locomotives as compared with 1,958 on June 30 and 811 on July 31, 1922.

BUILDING MATERIALS

The index of the cost of building materials entering into the construction of a six-room brick house, at 217 for July on a 1913 base, compares with 215 for June and 184 for July a year ago. For a six-room frame house the index for July is 214 as compared with 212 for June and 181 for July, 1922.

Contracts awarded for all classes of construction in 27 Northeastern states amounted to \$274,225,000 as compared with \$323,559,000 in June and \$350,081,000 for July a year ago.

The production of Douglas fir in July totaled 461,532,000 ft. as against 567,626,000 in June and 476,199,000 in July, 1922. Prices of lumber and building materials declined during the month while new orders for flooring, both oak and maple, increased in July over the preceding month.

CEMENT PRODUCTION

Production of cement totaled 12,620,000 bbl. as compared with 12,382,000 bbl. in June and 11,557,000 bbl. in July a year ago. Stocks at the end of July amounted to 8,076,000 bbl. as compared with 8,433,000 bbl. on July 31, 1922.

The total employment in 1,428 representative United States factories amounted to 2,041,250 on July 31 as compared with 2,040,827 at the end of June and 1,729,826 on July 31, 1922.

Wholesale prices in general declined. The Department of Labor index for 404 commodities being 151 as compared with 153 for June and 155 for July, 1922. The cost of living index, based on July, 1914, as 100, stood at 162 for July, as compared with 160 for June and 156 for July a year ago. The index of unfilled orders for basic commodities compiled by the Department of Commerce stood at 68 on Aug. 1, based on 1920 as 100, as against 77 on July 1 and 66 on Aug. 1, 1922.

Structural-Steel Sales

The Department of Commerce has just announced July sales of fabricated structural steel, based on figures received by the Bureau of the Census. Total sales of 113,331 tons were reported for July by firms with a capacity of 224,640 tons per month.

Tonnage booked each month by 175 identical firms, with a capacity of 229,575 tons per month, is shown below, together with the per cent of shop capacity represented by these bookings. For comparative purposes, the figures are also prorated to obtain an estimated total for the United States on a capacity of 250,000 tons per month.

	Actual Tonnage Booked	Per Cent of Capacity	Computed Total Bookings
1922			
April.....	200,588	87	217,500
May.....	184,638	81	202,500
June.....	168,498	73	182,500
July.....	157,651	69	172,500
August.....	156,011	68	170,000
September.....	146,146	64	160,000
October.....	132,450	58	145,000
November.....	111,704	49	122,500
December.....	138,024	60	150,000
1923			
January.....	172,415	75	187,500
February.....	163,938	80	200,000
March.....	218,997	95	237,500
April.....	185,355*	81	202,500
May.....	131,291*	57	142,500
June.....	116,609**	51	127,500
July.....	113,311***	50	125,000

* Reported by 174 firms with a capacity of 229,375 tons

** Reported by 170 firms with a capacity of 228,160 tons

*** Reported by 156 firms with a capacity of 224,640 tons.

Apprenticeship Courses Planned for N. Y. Building Trades

Registration will begin next month for the apprenticeship courses in the building trades in New York, as a result of co-operative effort between the Board of Education and the Apprenticeship Commission of the New York Building Congress. Through the medium of seventy night classes to be held in ten schools, an effort will be made to relieve the shortage in skilled labor by the training of young men as bricklayers, carpenters, sheet metal workers and painters.

It is understood that the bricklayers' union and the Mason Builders Association have promised their help in developing and carrying on a comprehensive apprenticeship program in the bricklaying industry. Similar movements are under way in Boston, Philadelphia, Cleveland and other cities, according to Fred F. Moran, managing director of the Apprenticeship Commission of the New York Building Congress. For the New York courses an enrollment of about 2,000 apprentices is expected.

The movement to develop apprentices by co-operation of employer, labor union and the public school system, according to Mr. Moran, is growing rapidly. It is said that employers who were formerly reluctant to take on boys to learn a trade, or who dispensed with them after a few months' trial, are now pledged to support the apprenticeship program. Recent conditions in the building industry have indicated the desirability of a steady, normal supply of apprentices to replace vacancies in particular trades.

Building congresses are functioning in various cities to stabilize the industry by developing an adequate supply of skilled labor and providing steady work.

Report on Surplus Freight Cars

The railroads of the United States on Aug. 14 had 78,404 surplus freight cars in good repair and immediately available for service if needed, according to reports filed Aug. 25 by the carriers with the Car Service Division of the American Railway Association. This was an increase of 4,236 over the number of such cars on Aug. 7.

Of the total number, 56,948 were surplus box cars in good repair, an increase of 1,582 within a week, while there also was an increase within the same period of 200 in the number of surplus coal cars, which brought the total number for that class of equipment up to 6,293.

The reported car shortage on Aug. 14 amounted to 8,315 cars, a reduction of 1,834 compared with the total on Aug. 7. Shortage in box cars amounted to 2,329, a decrease of 833 within a week, while the shortage in coal cars totaled 4,193, a reduction of 704 under the reported shortage on Aug. 7. Reports showed practically no shortage in other classes of equipment.

Much Building Planned in Britain

Since Jan. 1, Trade Commissioner A. V. Dye reports to the U. S. Department of Commerce, the British Department of Labor has gathered statistics showing the estimated cost of building plans approved from 142 localities in the United Kingdom.

During the first six months of this year building permits in these 142 localities, comprising about one-third of the population of the United Kingdom, amounted to £20,346,700. In June, however, the estimated cost of such building plans approved was £3,861,700, as compared with the average for the previous five months of £3,300,000 per month.

Building is, so far, limited to dwelling houses and large office buildings and construction or re-modeling of general stores, of which there has been a considerable amount noticeable in London and the larger cities. Dwelling houses are limited to two classes of construction: Houses which are built by owners for their own occupancy, and houses which are built by large corporations, such as coal mining companies, to house their employees. In both cases these houses are built without regard to the economic rent derived from the expenditure, as it does not yet pay to build houses to rent. That building and construction in Britain is improving is also indicated by labor conditions in that industry, which showed an improvement in June. The number of unemployed in building and construction has dropped from 182,123 on Jan. 22, to 114,243 on June 25.

Weekly Freight Loading Shows Slight Decrease

Loading of revenue freight for the week ended Aug. 11, according to the Car Service Division of the American Railway Association, totaled 973,162 cars, a decrease of 59,968 cars under the week of Aug. 4, due to the observance

of President Harding's funeral. It was, however, an increase of 130,472 cars over the corresponding week of last year as well as 164,893 cars over the same week of 1921.

While the loading of revenue freight during the week of Aug. 11 for the country as a whole increased 15.5 per cent over the corresponding week last year, the largest increase was 19.2 per cent in the Eastern district, which includes the Allegheny and Pocahontas districts, partially due to decreased coal loading last year on account of the miners' strike.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 115 to 127, are the following:

Temple, Milwaukee, Wis., to Raulf Co., \$1,500,000.

Hotel, New York, N. Y., to Lynch Constr. Co., \$1,500,000.

Apartment, Long Beach, Calif., to Seefeldt Eng. Co., Los Angeles, \$1,470,000.

Hotel and apartment, Long Beach, Calif., to Seefeldt Eng. Co., Los Angeles, \$1,000,000.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 115 to 127, are the following:

Canal, Port Colborne, Ont., for Dominion Dept. Rys. and Canals, Ottawa, \$10,000,000.

Pipe line, Portland, Ore., Bull Run Reservoir, \$2,500,000.

Infirmary, Louisville, Ky., for St. Joseph's Infirmary, \$1,500,000.

Fill, Erie Canal, Cities of Albany and Watervliet, N. Y., \$500,000.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual biddings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Aug. 2; the next, on Sept. 6.

Steel Products:	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal
Structural shapes, 100 lb.	\$3 64	\$4 00	\$4 20	\$3 40	\$3 55	\$4 20	\$3 69	\$4 10	\$4 00

Linseed oil, raw, 5 bbl. lots, gal.	.98	—1 00	1.14	1.12	—1 02	1.25	—1.16	.86	1.26
Common Labor:									
Common labor, union, hour	75	35	50@ 5555
Common labor, non-union, hour	30	30@ 50	82½	50@ 55	35@ 50	.50	.50@ .62½	.35@ .40

Explanation of Prices:—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given: 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. Labor—Concrete laborers' rate, 93¢; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu. yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5½ x 8 x 11½. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 97.68). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.43; 6-in., \$119.

Changes Since Last Week

In keeping with the general unevenness that has characterized the market during the last few weeks, this week's line-up shows an improvement in steel and non-ferrous metals, and depression in cast-iron pipe and linseed oil. Higher production costs, consequent to a shorter working day at the steel mills, have resulted in a solidification of the mill base at around \$2.50 per 100 lb. for shapes and plates, and \$2.40 for bars.

A buying movement has developed in

steel rails, wire and tin plate, while greater activity is reported in steel pipe.

Seattle warehouses report a reduction of five points in black steel pipe discounts and a severe drop in cast-iron pipe prices. Atlanta also quotes a reduction of \$2 per ton in c-i. pipe.

Warehouse prices, generally, have shown little change during the week, especially in lime, lumber, clay products and concreting materials. Linseed oil,

however, dropped 2c. in San Francisco and Minneapolis and 8c. per gal. in Atlanta.

Despite the fact that the brick manufacturing season is nearing its close and that a coal shortage is also threatened, the price of brick at New York docks is a trifle easier at \$20 per M., wholesale, as against \$21, recently. Common brick has been quoted at its present level, in this market, throughout the first half of the current year.

Volume 91

NEW YORK, SEPTEMBER 6, 1923

Number 10

Another Earthquake Disaster

AS WE go to press the first news comes of another mighty, historic earthquake in Japan. Such reports as have filtered out of the almost isolated country are sufficient to establish the appalling magnitude of the disaster, though their details are confused and hardly credible. The rumors of the destruction of numerous modern steel-frame buildings clash sharply with all that has been learned from prior earthquake experience, and for the present at least must be discounted. But earthquake visitation is fantastically erratic, and the years during which its effects have been studied are short indeed, so that it is by no means impossible that the details of a new disaster may give the lie to past conclusions. However its full facts may develop, the present catastrophe is great enough to dispel any belief that earthquakes are growing less frequent and less terrible. Modern civilization has to reckon with them fully as much as did earlier ages.

The Coal Commission's Duty

SEPTEMBER first has come and with it the anthracite coal strike. In spite of all the elaborate preparations made to prevent a repetition of last year's strike—the formation of a federal coal commission and the interposition of the Governor of Pennsylvania—the Juggernaut car of the coal industry proceeds on its appointed way. It is hardly to be believed that the "little group of wilful men" on both sides of the table will really defy the American people another year, but if they do they must take the consequences of drastic action in the coming congress. One thing is incumbent now on the coal commission. That body presumably knows more about the coal business than any other group of unprejudiced men. The people at large know nothing about the rights of the controversy, but they are entitled to a frank statement from that commission as to who is responsible for the present conflict. One might wade through the volumes of testimony and statistics prepared by the commission and come to some conclusion but it is not a fair thing to ask. The commission knows, or ought to know, whether the operators are making too much, whether the middleman is a profiteer and whether wages and working conditions are unfair to the workmen. The commission is obligated by the situation to state definitely where the guilt of this outrageous strike lies.

Recognition of Mexico

NEGOTIATIONS looking to a renewal of diplomatic relations between this country and Mexico have been under way for some time and last week word came from Washington announcing the full recognition of the present Mexican government beginning Sept. 1. This event will have an important influence on prospective engineering development in Mexico. Some projects that have not yet been financed may now be regarded in a

more favorable light, American interests can expect better protection from their own government and, with American recognition, the Mexican government itself can be expected to look more favorably on development in Mexico backed by American capital. The recent start of construction to complete the gap in the railroad along the west coast will help conditions greatly; with direct rail connection through to Mexico City the danger of banditry in the heretofore isolated west will be lessened and there will be a means of transportation that will facilitate development. Perhaps the first and most attractive field for developments are in the oil and mineral resources of Mexico. These require but little exploitation. However, as soon as capital, particularly American capital, gains confidence, assurance of protection and an insight into the wealth, the extent and the variety of Mexican resources thus far practically untouched, there will certainly ensue an era of prosperity in which American engineers should have a generous share.

Light on Cement Prices

STATE authorities who are considering the construction of cement mills to reduce what they consider the high cost of cement will do well to study the figures on the profits of eleven of the large companies in the East submitted by Professor H. P. Willis, of Columbia University, and noted in the news pages of this issue. Doubtless Professor Willis will gladly furnish the full data on which he has based the figures that are given here, so that the state can check them for those items of investment and operation which should be of so much importance in any computation on the cost of state cement production. If private companies, with their wealth of expert aid and of experience, are unable to average more than 7.3 per cent earnings on their investment, there is certainly no reason why any state should consider prices so exorbitant as to enter into competition with them.

Shaded Topographical Maps

IF NEW methods of bringing out topographic relief on contour maps are successfully developed and brought into use, in pursuance of the present attempts of the Geological Survey, as outlined in this issue, the utility of what is sometimes spoken as the map of the United States will be increased in an almost sensational degree. Of the wealth of information contained in the contour map as now published, only a small part is readily available for use. For most kinds of topography the contour system beclouds and conceals rather than reveals the features of the country, and any general understanding of the lay of the land can be worked out only by previous detail study. This condition is a fatal bar to useful application of the map in a great number of cases where it would otherwise prove of value. Engineers, as well as other map users, have long felt the

desirability of some more plastic method of showing relief, preferably to be combined with contours in order not to sacrifice the numerical definiteness which these give. We believe that this feeling has grown decidedly in recent years, and that engineers in particular are anxious to have an improved system applied to the existing maps at the earliest possible moment. In selecting the best system and working out its details, however, the government authorities should be supported and guided by the opinion of map users. It is suggested that those who have definite opinions on the subject based on experience with topographic maps make their views available without delay, to assure the most rapid forwarding of the development of an improved system.

An Irregular Standard

LAST month we commented editorially on the extremes to which the enthusiasm for standardization can be carried. A minor, though illuminating, example has just come to notice. In this month's *Harper's*, in an excellent article on the railway problem, there is some preliminary comment on the establishment of the standard gage, in which the author by implication deplores the irregularity of the 4 ft. 8½ in. standard and is especially concerned over what he is pleased to call that "absurd one-half inch." This is characteristic of the craze for standards. It is assumed that there is some magically saving grace in even figures, that millions of dollars a year and thousands of useless brain throbs would be saved by an even 4-ft. or 5-ft. gage—all of which is just as absurd as that one-half inch is claimed to be. Fifty six and one-half inches is just as easy to remember and just as easy to measure as five feet, as every engineer knows and while one may be curious to know how the standard gage was arrived at certainly no railway man would go to any great trouble to change it to an even figure.

Not All Profits

TRAFFIC through the Panama Canal is increasing in surprising volume. In the nine years of its operation, which were completed last month, the paid tolls, which are a fair measure of traffic, amounted to \$76,000,000. Of this amount \$17,000,000 or 22 per cent were in the latest fiscal year. In the latest month the tolls were somewhat over \$2,000,000, as against the average monthly for the nine-year operation of about \$700,000. Taking these figures as a text, Governor Morrow, of the Canal Zone, who recently arrived in this country on his annual trip to Washington, has been extensively quoted in the daily press as stating that the Canal is now paying better than 3 per cent on its investment. This is hardly a fair statement, whether Governor Morrow said it or not. The government now has invested in Panama, according to the latest figures, upwards of \$450,000,000, of which \$400,000,000 can be probably charged to the Canal itself, the other \$50,000,000 being bookkeeping liabilities which probably have compensating money assets. This extends back over a period of nearly twenty years. On even so low a rate as 3 per cent the investment has piled up in an average of ten years about \$120,000,000 interest charges which in any private business would have to be accounted for in figuring profits. It is highly gratifying to everyone who favored the construction of the canal that it is now bringing in, clear of expenses, an income of approximately \$500,000 a

month. Even were the financial return not so great the value of the Canal would be unquestioned. It cannot be fairly said, however, that it is bringing in a profit on the investment except on the basis that all such government expenditures have their own type of accounting which does not come in the same realm of mathematics as that of private business.

Highway Accidents at Railway Crossings

EXAGGERATED importance is likely to be attributed to the railway crossing as a cause of highway accidents unless one holds his perspective true. Horror is aroused by their deadliness and by the complete demolition which usually results. A contributing reason perhaps is the fact that so few automobile accidents are due to other faults of road structure. Crossing accident figures are undoubtedly impressive. The Interstate Commerce Commission for the last quarter of 1922 reports 517 deaths and 1,710 other casualties due to this cause. This is a condition that obviously calls for change. Quite as obviously the only certain and complete remedy is grade crossing elimination. Eventually we must come to this perfect cure. Always its adoption should be urged. Always also, it has to be remembered, it is an enormous physical and financial task which cannot soon be accomplished and it is a primary duty meanwhile to undertake palliative measures. Our railway crossings are yet far from being properly protected by signals and barriers. Careless driving which is the major cause of all highway accidents has scarcely begun to be curbed. Statistics are not plentiful but all that can be found agree very closely. In Iowa in 1922 there were 6,513 highway accidents which involved casualties, and of these only 4½ per cent were at grade crossings of railways. Referring to the total figure the state highway commission bulletin concludes that "reckless and careless driving would seem to be the cause of 90 per cent." In Wisconsin in eight months of 1922 there were 1,069 accidents of which 6½ per cent were at railway crossings. Again something over 70 per cent of all were due to careless driving. In every way the task of curbing reckless and careless driving is more imminent than that of producing accident-proof road structure including even the deadly railway crossing.

New York Garbage and Jersey Beaches

COMPLAINTS of New Jersey sea coast towns that their beaches are strewn with the garbage and refuse of New York City bring to mind the fact that it is now some five or six years since our largest American city returned to the primitive means of dumping its garbage and refuse at sea. In doing this it abandoned an engineering plan the main features of which were worked out by the late Col. George E. Waring, after extended studies by a staff of specialists—a plan also which in the main has been recommended for New York by other engineers after careful investigation. Not only that: the contractor whose garbage reduction plant in New York Harbor Mayor Hylan caused to be shut down was under agreement to pay the city for every ton of garbage the city delivered to the plant, while since the change the city has been paying for barging the garbage many miles farther to be dumped at sea, whence, according to the Jersey shore cities, it floats inshore to become a nuisance and to lessen the summer crowds on which the residents of these towns live.

Upon the controversy as to whether the beach litter comes from the city scows or seagoing vessels, we cannot undertake to pronounce. The fact of general engineering interest is that the largest city in the two Americas has for a half dozen years allowed its refuse disposal problem, and the refuse itself Jerseyites claim, to drift, while at the same time paying out large sums annually for dumping garbage containing grease and fertilizer base for the recovery of which a contractor was under agreement to pay the city. We are well aware that the contractor was in financial straits; that the plant was ordered closed because of allegations of nuisance; that the contractor did not contest the order—perhaps because the plant was losing money; and that the war garbage reduction, like pig feeding and incineration, has had its ups and downs—mostly downs. Notwithstanding all this, the city's action appears to have been grounded on pre-election controversies and promises and on political reprisals rather than on engineering considerations.

The present situation is accompanied with the usual wild statements about the relation of garbage disposal to the public health. Thus, Governor Silzer of New Jersey, according to a reporter's story in the *Newark News*, has "traced the appearance of a form of intestinal grip to germs in the garbage dumped from New York City." Can it be that Jerseyites are eating garbage these summer days? Worse than this—because it is an editorial utterance, and editors are supposed to show knowledge and judgment—the *New York Times*, after discussing sympathetically the Jersey coast allegations against New York garbage, turns to what it regards as New York's laxness in sewage disposal and closes with saying that the city is "apparently willing to continue its old makeshift system until some calamity, such as an epidemic directly traceable to pollution [of salt water, be it noted] shakes the authorities out of their apathy."

It is just this sort of tilting at men of straw indulged in to arouse public opinion to the need for better garbage or sewage disposal that is largely responsible for such apathy as exists. The cry of "wolf, wolf" soon fails to alarm. Some ill-informed and unthinking people may be roused to momentary excitement over "epidemics," threatened by a dead cat in the street, garbage on a bank of snow in the dead of winter, watermelon rinds on a beach, "sewage slick" in a harbor, or offensive sights and odors in dock slips or alongshore; but the underlying commonsense of the people at large and the experience of communities as well discounts such alarmist outcries. The taxpaying public and city authorities responsible for it will spend money to insure the purity of their water supply and, as enlightenment progresses, of the milk they drink, because they have experienced to their sorrow that impure water causes typhoid and contaminated milk results in typhoid, infant mortality, tuberculosis, and other ills; but subconsciously, at least, they know that garbage and sewage, once these wastes are well clear of their homes, will, as a rule, produce nothing worse than bad sights and smells—barring the pollution of public water supplies, which is now generally well guarded against by one means or another. When the smells are bad enough, or a community becomes unusually sensitive or supersensitive to them it will, on that account but not because of real and well grounded health fears, appropriate money for improved means of sewage and garbage disposal.

New York today, to return from the general to the particular, is spending large sums for a primitive means of garbage and refuse disposal; but it is only fair to add that under existing conditions affecting both the incineration and reduction of garbage it is conceivable, until competent engineering studies demonstrate the facts one way or the other, that New York's refuse might be towed so far out to sea as to insure its never or rarely returning to shore, at less than the net cost of reduction or the cost of incineration, though for the latter there is little promise of revenue in the light of all American experience and of British experience of recent years. It is also only fair to the New York authorities to say that progress is being made on a systematic plan for sewage disposal.

Garbage and refuse disposal problems are more than ever for engineers to solve and for politicians to let alone, except as the latter choose from possible engineering methods the one most likely to meet the demands of an intelligent public opinion rather than of political expedience or revenge.

More to Come on Earth Dams

THE Apishapa Dam, the failure of which was noted in *Engineering News-Record* last week, bids fair to become a celebrated case in dam engineering. Earth dams of such height and volume are always an interesting problem, because their design and construction continue to be more empirical than in other types of dams, and failure is important in the development of the art of their design because by failure alone can there be absolute assurance that something went wrong. To discover just what that something is is the difficult sequel of all such dam failures.

In the Apishapa case this is the outstanding fact at present. There are so many inconsistencies and contradictions in the various reports that have come in to *Engineering News-Record* that it has been decided to postpone publication of any of them until next week, or a future time when a fair degree of consistency in the reports can be assured. Two important details, however, may be noted for future reference. The first is the diametric opposition as to the desirability of early filling of the reservoir behind dry fill earth dams and the second is the historical significance of the protests of the designing and constructing engineer during the construction of the dam.

One observer writing in claims that to leave dry such a dam in the arid west is to invite failure by sudden filling of the reservoir. The designer, on the contrary, stipulated in his preliminary reports that the reservoir should not be filled for some years, during which time the dam was to be allowed to settle and densify. Here is obvious contradiction that needs explanation and it is on a point which is most pertinent to the design of the dry emergency dam such as built at Dayton and planned at Pueblo.

The designer's ungranted plea for additional height and section, with his subsequent disclaimer of responsibility in case of failure, has a dramatic element not usually associated with the prosaic business of dam building. Whether or not the failure was due to matters he wanted corrected remains to be seen, but he is at least entitled to his day in court. His interpretation and the full reports on the failure should be important contributions to the art of earth dam building.

A Bascule Bridge of New Type and Its Construction

Varying Effective Length of Hanger Link Maintains Balance—Bull-Wheel and Worm-Gear Operation—Toe Locks Eliminated—Creosoted Lumber Framed and Bored at Mill

BY THOMAS E. BROWN, JR.
Consulting Engineer, New York

AND WILLIAM G. GROVE
American Bridge Co., New York

SEVERAL unusual features distinguish a new bascule highway bridge at Mystic, Conn., completed last year. It is the first bridge of a newly developed type, in which the counterweight rotates through a considerably smaller angle than the span. At Mystic the counterweight rotates through an arc of only 69 deg. while the span is traversing a full right angle. This is accomplished by means of a double-pivoted short link

terurban trolley line, together with considerable pedestrian traffic. To meet the traffic needs, a roadway width of 33 ft. in the clear was provided, with a single trolley track in the center. The roadway is paved with creosoted wood block. The sidewalks are 5 ft. wide and are paved with a 3-in. reinforced-concrete slab. (Fig. 2 shows a cross-section of the movable span.)

Selection of Type—In the selection of the particular type of bridge for the opening, various types of movable spans were considered. The required channel width was 75 ft., with a clear vertical height of 135 ft.; this rela-

FIG. 1—GENERAL PROFILE AND PLAN OF NEW BROWN BASCULE HIGHWAY BRIDGE AT MYSTIC, CONN.

forming part of the hanger link, and a stop on the moving-leaf girders which changes the effective length of the hanger link during the motion. The small angle of rotation of the counterweights permits of their being placed symmetrically about the center lines of the balance beams without interference with the tower, and keeps girder, tower, balance beam and counterweight all in the same plane, obviating the necessity of carrying loads transversely.

A bull-wheel method of operation is used, which incidentally locks the span in its closed position. Worm gears are successfully employed, eliminating the noise of high-speed spur gearing. Special details were introduced to permit the concrete sidewalks and wood-block roadway paving to be raised with safety to the vertical position. The counterweights were poured in their high position with a small under-support. Framing and boring of the creosoted lumber at the mill was used with success.

General Description—The completed bridge consists of four through plate-girder spans; the main or movable span of 84 ft. 8 in., a tower span of 23 ft., and two simple approach spans. (Fig. 1 shows profile and plan of bridge.) The bridge is on the New York and Boston Post Road and carries traffic of large volume and heavy weight, including motor trucks and a single-track in-

tively great height of channel clearance compared to the length of span excluded the vertical lift. The extreme width of the bridge, practically 50 ft. over all, would require a swing span at least 210 ft. center to center of end wedges if the bridge were made symmetrical with both arms of equal length. However, as buildings at both ends of the bridge extended up to and in some corners in front of the abutments, and a symmetrical swing span would have extended about 25 ft. over the west abutment, a bobtail swing would have been required, which in turn was prohibited by the location of the center pier and the channel.

The elimination of the swing and vertical-lift types necessitated the use of some kind of a bascule, and after careful consideration and comparative estimates it was decided to adopt the Brown "balance-beam" type. There are several advantages of this type over the older forms of bascule, and as the bridge at Mystic is the first of its kind to be built a short description of the method of balance is of interest.

The movable span is counterbalanced by two concrete weights placed on the center lines of the main girders and carried by balance beams in the form of trusses which rest on trunnions at the tops of the tower bents. These trusses are about 60 ft. long over all, and their forward ends are connected with the plate girders of

the moving span by hanger links or suspenders consisting of eyebars and short links having double sets of pivots at the span end. (See Fig. 3.) Butt blocks or stops are suitably placed on the upper flanges of the movable-span girders to make contact with the short links at the proper time during motion, and thus change the point of rotation of the eyebar hangers from one set of pivots to the other. This system of multiple pivots is the important distinguishing feature of the new Brown type.

Fig. 4 is a diagram showing the action of the pivots and butt blocks as the span rotates through its 90 deg. of motion. Between positions I and II of the span (see Fig. 4), or for about the first 38 deg. of motion, the hangers rotate about the primary pivots *A*. The butt blocks then make contact with butt castings on the short links, preventing their further rotation about pivot *A*, as shown in position II. From this position throughout the remainder of the opening, the eyebars rotate about the pivots *B*, on the ends of the short links.

It will be noted in Fig. 4 that in the closed position of the span, when its center of gravity is horizontally in front of its trunnion, the center of gravity of the counterweight is well above the level of the balance-beam trunnion, and that in the open or 90-deg. position, when the span is vertical, the counterweights are considerably back of the vertical tower legs and entirely clear them; that is, the span has rotated 90 deg. while the total angular motion of the counterweight is only 69 deg. Throughout the entire motion no attempt is made to keep the lever arms or the angular motions of the span and of the counterweights about their respective trunnions equal or similar in any way, the balance being maintained entirely by selection of the pivotal points *A* and *B* so as to reduce and increase the respective lever arms of the hanger links about the balance beam and the span trunnions in proportion as the moments of the counterweights and the span vary about their respective trunnions.

There are several advantages with these two pivotal points of rotation. The counterweights, not having to pass between the tower legs, can be built centrally over and integral with the balance-beam trusses; thus all the stressed members from girders to counterweights are maintained in the same plane, saving a considerable amount of steel usually required for lateral transfer of forces or of counterweight loads. The counterweights being in two sections entirely disconnected, no

FIG. 3—SHORT LINK AT BASE OF MAIN EYEBAR HANGER

This link in conjunction with the butt-block on the girder, in the foreground, changes the leverage of the counterweight as the span rises.

rigid bracing is required between the balance beams. Light bracing only is required, which though rigidly providing against lateral overturning of the beams yet allows a slight flexibility of motion in the planes of the trusses and thus provides against the possibility of binding of trunnions or pins and against inequality of stress in the hangers due to the usual slight inaccuracies in lengths of members and in lining up of trunnions in the field.

Again, there is great latitude in the choice of the positions of the points *A* and *B* while retaining the practical balance throughout the motion. In the Mystic

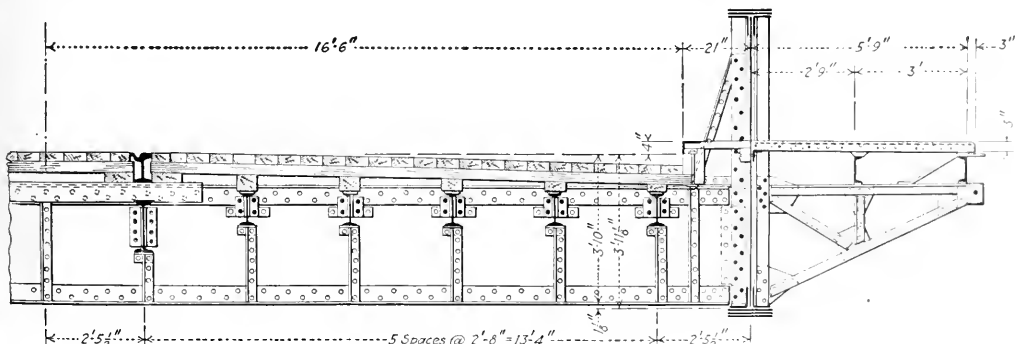

FIG. 2—HALF CROSS-SECTION OF BASCULE SPAN

design point *A* was so chosen as to provide an unbalance when closed, tending to hold the bridge well down on its toe bearings, which in combination with the locking function of the bull-wheel avoided the necessity of toe locks. This positive reaction at the toe end is 1,000 lb. per girder. Point *B*, on the other hand, was placed slightly higher than the theoretical position required. This increases the backward or downward pull of the hanger around the span trunnion (see Fig. 4), offering a resistance to the further opening of the bridge as it approaches the 90-deg. position. The resistance increases rapidly if the span passes the vertical, thus providing a safety factor against the span being blown or operated backward against the tower.

A further advantage is the adjustability of point *B* by shimming in the butt block to obtain nicety of balance or to compensate for a change in dead load of the floor.

Power Equipment and Machinery—On the Mystic bridge the main source of power is three-phase 60-cycle alternating current delivered at 2,200 volts to the bridge site, where it is transformed to 220 volts. Operation is by two 36-hp. motors of the induction type, one on each side of the tower span, placed on unit frames with worm-gear units of a ratio of 20 to 1. By the use of worm-gear units the operating machinery was made so compact

FIG. 4—DIAGRAM SHOWING ACTION OF BUTT BLOCKS

as to enable it to be placed below the sidewalks on the tower span, because from this worm reduction only two spur gears were required to reduce to the pinion which meshes with the teeth on the periphery of the bull-wheel. An additional advantage in the use of worm gears is that they avoid the necessity for high-speed spur gearing, and hence the operation of the bridge is remarkably smooth and noiseless.

The bull-wheels and their pinions are in the planes of the tower bents, and the forward ends of the bull-wheels are connected by links or "connecting rods," which straddle the front legs of the tower, to operating pivots on the main bascule girders. The lengths and

FIG. 6—FORMS FOR COUNTERWEIGHTS

positions of these links are so adjusted that when the bridge is in its closed position they are practically on dead center with the axes of the bull-wheels, thus locking the bridge in this position (see Fig. 5). This bull-wheel lock in combination with the unbalance of the span, already described, enables toe locks to be dispensed with. The bull-wheels also provide greatly increased leverage at the two extreme positions of the span. As the operating links approach the dead-center position at the extreme ends of the run, the combined leverage of the machinery approaches infinity and the speed of the span approaches zero. This permits very gentle seating of the span with motors running at constant speed. In fact if, through inadvertence on the part of the operator, the motors should continue to run after the span is seated, the links will pass the dead-center position and open the bridge, instead of stalling or short-circuiting the motors. Likewise in open position, when the span offers the greatest wind-sail area, the operating links have reached the other point of increased leverage, which condition combined with the automatically increased unbalance of the span makes it an impossibility for the span to be overturned against the tower, regardless of the wind velocity.

The two independent machinery reductions on each side of the bridge are connected by the usual transverse shaft. The motor shafts are equipped with solenoid brakes, and in addition emergency air-brakes are provided on each end of the transverse shaft. Either set of brakes may be used independently. The usual emergency hand operation is also provided.

Erection—On account of the extreme simplicity of the structure no particular problems were encountered in the erection with the exception of the placing of the concrete counterweights. The original design had been made with the idea of erecting the bridge in open position, for which purpose the approach span at the rear of the tower had been designed with a view to supporting the forms and the counterweights while the latter were being poured in their lowest position, with the center of the counterweight 9 ft. from the center of the pier. But it was found much simpler to lay the concrete sidewalks and wood block paving with the span horizontal so that the decision was later reached to erect the entire span in the closed position.

The counterweights therefore had to be built in their upper position, in which they were a horizontal distance of 24 ft. from the pier and about 32 ft. above the roadway. The approach-span girders were not sufficiently

FIG. 5—BULL-WHEEL

strong to support the entire weight in this position with the additional framework required. The solution of the difficulty was to carry the greater part of the load from the balance beams.

This was accomplished by putting up light staging on the approach span, sufficient to carry the weight of the forms and also the weight of a 2-ft. bottom slab of concrete; then, before pouring this bottom slab, wire guys or tie ropes were attached to the top of the balance beams and brought out through the bottom of the forms. After the bottom slab had set, the remainder of the concrete was poured. Fig. 6 shows the counterweight forms.

The requirement that the span must open to 90 deg. necessitated considerable care in the laying of the wood-block paving and the concrete sidewalks. Each individual block on the lift span was separately nailed to the sub-planking with a wire nail through the center of the block. In addition, horizontal angles about 10 ft. apart were laid on both roadway and sidewalks, to act as shelf angles supporting independent 10-ft. sections of the wood-block paving and concrete when the span is in the open position.

A special feature in connection with the field work was the boring and framing of nearly all of the creosoted lumber at the mill, although cutting and boring before creosoting was not required by the specifications. Steel erectors are averse to handling creosoted lumber, and it was therefore decided to relieve them of a large portion of this work. The spiking pieces, curb guards, ties and other miscellaneous lumber were framed and bored before creosoting, so that very little field work was necessary, the principal part being the boring where steelwork or other bored lumber was used as a templet. The lumber was given marks at the mill similar to shipping marks on steelwork. The erection department was well pleased with this method of handling the lumber, as it saved considerable expense and time besides relieving the erectors of an uncongenial task.

Conclusion—The total weight of steel in the bridge is about 400 tons; the weight of the moving leaf complete is about 200 tons. The concrete counterweights weigh 400 tons, while the total weight of the moving parts is about 650 tons.

The bascule and tower spans were designed by Thomas E. Brown & Son, consulting engineers, for Waddell & Son, who were consulting engineers to the

state highway department for this portion of the work. The approach spans and the substructure were designed by the state highway department, L. G. Sumner, chief draftsman. The substructure work was done by the J. E. Fitzgerald Co.; the structural steel superstructure and machinery were fabricated and erected by the American Bridge Co.; and the concrete counterweights were placed by the C. A. Sibley Co. The bridge was built for the state of Connecticut under direction of Chas. J. Bennett, formerly highway commissioner, R. L. Saunders, formerly deputy commissioner, A. W. Bushnell, district engineer, and A. R. Collier (now state supervisor of bridges), resident engineer.

Camp Site Sanitation in Wisconsin

DUE to the thousands of tourists who camp out in free sites maintained by cities as one of the summer attractions for patronage, attention has been given in Wisconsin to safeguard public health and insure comfort for the patrons. In a recent bulletin issued by the State Board of Health the following essentials in campsite sanitation are noted:

- (1) Provide a safe water supply such as wells or springs protected from pollution. Have the water analyzed before the season opens.
- (2) Adequate sanitary toilet facilities should be maintained.
- (3) Provide garbage and refuse receivers and a daily disposal. If there are no containers, bury or burn the waste.
- (4) Maintain clean premises and equipment.
- (5) Enforce rules conspicuously posted governing use of grounds.
- (6) Eliminate fleas and vermin by every means available.
- (7) Employ a caretaker and give him authority to enforce sanitary regulations.

It is encouraging, say the health officials, to note that the municipalities boosting campsites are shaping their plans toward the observance of these rules and in not a few places have these ends been achieved.

Syracuse Garbage Reduction Works Reopened

The Syracuse garbage reduction works, which were shut down for some months, were reopened in the latter part of June, after having been remodeled. The works are being operated under a five-year lease made after the city had advertised for bids. The contract, which included also a certain amount of remodeling, was awarded to the C. O. Bartlett & Snow Co., Cleveland, Ohio, which organized the Cobwell Reduction Co., a New York corporation, to carry out the terms of the contract. The city pays the company \$30,000 a year to cover both operation and amortization of the cost of remodeling the plant, the capacity of which was increased to 125 tons per day or more than double the original capacity of the plant as built by the city. In the plant as it now stands, the garbage is first shredded and then fed to the dehydrators, both operations being mechanical. The dehydrators are of indirect-direct heat type. They reduce the free moisture content to about 30 per cent. In the dehydrators the remaining moisture is eliminated, the material is broken down under low temperature and the grease extracted, all this work being done as a continuous process within the closed receptacle. After the process thus outlined is completed, the remaining solid material is screened and then conveyed to storage.

FIG. 7—MYSTIC BASCULE PARTLY OPEN

Iron Removal and Softening Plant, Benton Harbor, Mich.

Preliminary Experiments Indicated Use of Lime
for Reduction of Iron Carbonates—
Softening Added to Process

NOVEL features of the iron removal plant at Benton Harbor, Mich., comprise mixing chambers equipped with stirring devices and so arranged that a portion of the water delivered to the plant may be over-treated with lime before being mixed with the remaining portion. The stirring devices themselves in the mixing chambers are not entirely new as these were probably first used on a municipal plant by Philip Burgess at Owensboro, Ky. Over-treating a portion of the water was suggested by the experience at the Grand Rapids filter plant. The combination of the arrangement and equipment, however, is believed to be rather unusual. Another feature, first suggested by C. P. Hoover, is the use of a Dorr thickener in the sedimentation basins. This clarifier has two functions: (1) It removes the

FIG. 1—IRON REMOVAL AND SOFTENER PLANT

bulk of the sludge continuously so as to reduce the number of times that the sedimentation basins must be emptied and cleaned. The peculiarities of the locality are such that this operation involves pumping out the lower portions of the sedimentation basins, an operation which is costly, time consuming and troublesome. (2) Means are provided for returning a portion of the settled sludge to the raw water so as to promote rapid reaction and precipitation of the lime with the bicarbonates in the water.

The plant has a nominal capacity of 2 m.g.d. Under this rating the mixing chambers have a retention period of 50 minutes, the Dorr clarifier 1 hr., and the sedimentation basins 8 hr. A clear water storage of 700,000 gal. is provided.

Hitherto the city obtained its public water supply from wells in the sand and gravel beds bordering the St. Joseph River. The yield of these wells was not sufficient to meet maximum summer demands. Moreover, the water contains some 2 p.p.m. of iron which caused very objectionable staining of plumbing fixtures and also favored the growth of crenothrix in the mains. The water carries about 250 p.p.m. of hardness, all in the form of carbonates of calcium and magnesium. The magnesium content is high, about 23 parts per million.

The city authorities decided to utilize the St. Joseph River as a source of water supply, as being the most certain in point of quantity and the most economical. It was proposed to render the water of good sanitary

quality by purification. Lake Michigan water would have been preferable because it is generally materially softer than the river water, but the distance to Lake Michigan rendered this project unduly expensive.

The principal objection to the river water is its warmth in the summer time and there is also a sentimental objection to its sanitary quality even if it is not delivered into the mains until passed through a filter plant. To obtain the advantages of both the well water and the river water it was decided to build a plant which could be utilized to remove the iron from the ground water or purify the river water. Preliminary experiments that were conducted with a view to determining the best design and proportions for a plant for removing the iron from the ground water revealed the necessity of using lime to precipitate the iron. This suggested the desirability of softening the water, as the hardness is in the form of carbonates in both river and well water. Accordingly, the functions of the plant were enlarged to include partial softening—partly for economy and partly because it was believed that if the water is reduced in hardness to a Lake Michigan water standard, it would prove satisfactory to all concerned.

The experimental plant comprised the usual component parts of a rapid sand filter plant; coagulant preparation and feed devices, mixing chamber, sedimentation basins and rapid sand filters. In addition, a 10-ft. gravel filter or adsorption tower, a lime saturator and an aerator were included. One set of experiments without chemicals of any sort indicated that aeration and 4½ hr. of sedimentation had no material effect on the removal of the iron. However, the iron was taken out almost completely in the sand filter. This method of treatment was regarded as objectionable since accumulations of iron and crenothrix growth in the filter may be anticipated which would tend to unfit the filter for the treatment of the river water.

Another series of experiments with alum as a coagulant was unsatisfactory. The sedimentation basins failed to take out any material amount of iron and it was found practically impossible to obtain a good alum floc. The mechanical filter, as in preceding experiments, removed the major portion of the iron.

Experiments with the use of lime developed what the engineers regard as a satisfactory method for removing the iron. After the application of lime the sedimentation basins were able to reduce the iron from 1 to 0.2 or 0.3 p.p.m., which was carried to somewhat less than 0.1 p.p.m. by the mechanical filter.

FIG. 2—DORR THICKENER FOR SLUDGE REMOVAL
Continuous instead of intermittent removal of sludge is obtained in the water purification plant by adapting sewage apparatus to the water purification process.

FIG. 3—MIXING CHAMBERS OF 1-HR. DETENTION PERIOD
Four units with motor-driven stirrers. In background at left are three chemical dry-feeders.

Further experiments were conducted to determine the efficacy of back treatment with alum to prevent incrustation of sand grains. It was observed in the experiments that whenever there were normal carbonates in the effluent from the sedimentation basins a reduction in alkalinity took place during the passage of the water through the filter.

The adsorption tower was found to reduce the iron to 0.3 or 0.4 p.p.m., with rates up to 250 m.g.d. per acre. The tower experiments were not pursued to a finality, as it was found feasible to remove the iron with ordinary devices included in a rapid sand filter. They may, however, prove of value elsewhere especially if some satisfactory means can be devised for cleansing.

Both experimental work and subsequent design and construction of the combined filter and softener were carried out under the direction of Pearse, Greeley & Hansen, consulting engineers, Chicago.

Observations on the Failure of Structural Materials

Japanese Tests Point to Influence of Internal Friction and Indicate a Constant Angle of Friction

BY GEORGE PAASWELL

Consulting Engineer, New York City

THE PHENOMENA attendant upon failure of structural units are usually dismissed by the engineer with the thought that, being without the province of elastic law, they can have no bearing upon elastic stress distribution. As a matter of fact, it is now becoming recognized that tests to destruction serve to show more than mere maximum loads. A recent paper by Chidō Sunatani (in "Technology Reports of the Tohoku Imperial University, Sendai, Japan," Vol. III, No. 1, 1922) serves to illustrate the fact that the study of the failure of stressed bodies may modify accepted notions of elastic behavior and limit permissible stresses to certain ratios of the fundamental shear and tension stresses.

Engineers are beginning to recognize that, however complicated the applied stress distributions, impending failure is controlled by the elementary shear or tension stresses on planes determined by the maximum-stress theory of ordinary elastic law. Failure tests aid in indicating how such surfaces of maximum stress may be located. Thus cylinder tests for compression on con-

crete illustrate shear failure, not compression failure, and the permissible compression stress is really the permissible shear stress from the applied load.

When does a body fail? There are three theoretical criteria upon which failure is assumed to depend. Failure is believed to occur either (1) when the applied load reaches a certain value, the criterion of maximum stress; (2) when the elongation in the direction of the load reaches a certain amount, the criterion of maximum strain; or (3) when the maximum shear due to the load reaches a certain value, the criterion of maximum shear. According to the first two, failure surfaces should be normal to the applied load; according to the third, failure surfaces should make an angle of about 45 deg. with the load axis, depending somewhat on the nature of the material (brittle or ductile).

As a matter of fact, tests verify none of these deductions. Mr. Sunatani has conducted a series of torsion, tensile and compressive tests, and has found failure surfaces that seem to depend upon an angle of internal friction ϕ . Previous investigators (Mohr, Hartmann, etc.) have recognized the possibility of internal friction in elastic structures, and the appearance of Lüder lines in a tension specimen of ductile material is explained on a frictional theory. It is questionable whether such internal friction assumes an important rôle within the yield point; but at or near failure, Sunatani demonstrates quite clearly, internal friction does play an important rôle.

Two types of failure are distinguished: a sliding failure, such as occurs in brittle material under compression, and a tensile failure, such as a brittle material would suffer under simple tension. The failure of a ductile material under tension exhibits some of each type of failure, the outer shell of the specimen yielding to a sliding failure, the inner core to a tension failure.

For the case of sliding failure, the determination of the maximum stress is made upon the basis of a shearing resistance in the failure plane (the usual tangential component of stress) and the frictional resistance (which is the product of the internal friction coefficient k , or $\tan \phi$ and the normal stress on this plane). Determining the plane upon which this composite stress becomes a maximum, the author finds that for simple tension, sliding occurs along a plane making an angle of $45^\circ - \frac{1}{2}\phi$ with the axis of the tension load, and the shearing stress, R , bears the following relation to the applied unit stress, t :

$$R = \frac{1 + \sin \phi}{2 \cos \phi} t$$

If the applied loading is compressive, the numerator of the equation takes the form $1 - \sin \phi$. For a torsion load, where f_s , the torsional shear, is obtained from

$$f_s = -\frac{3M + a \frac{dM}{da}}{2\pi r}$$

(M is twisting moment, a is angle of twist, and r the radius of the member), the limiting shear of sliding failure is

$$R = f_s \cos \phi$$

Here f_s and t are stresses that may be computed from usual tests, the former by means of the equation just given, the latter by taking the quotient of the applied load and the area of the section. Since the controlling shearing stress R is the same for either case, the angle ϕ may be obtained from

$$\sin \phi = 2 \frac{f_s}{t} - 1$$

With the ratio of the unit stresses as obtained by tests upon the same material for torsion and for compression, the author finds that the shear stress is about 0.7 of the tension stress, which gives a value for ϕ of approximately 20 deg. Measurements of the angle of the fracture planes of wrought iron, mild steel, brass and copper, indicated with experimental exactness that this is a correct value of the angle.

In similar fashion the author derived an expression for maximum tension on a plane, the resistance of the plane being controlled by the normal tension stress as indicated by usual elastic theory, and a tangential frictional component, the product of the internal friction coefficient k and the shear stress. This formula indicates failure surfaces making angles of $\frac{1}{2}\phi$ with the horizontal. Tests upon brittle specimens, such as plaster, chalk and cast-iron, again gave a value of the internal friction angle of 20 deg. That this angle appears constant leads the author to state that "the effect of the normal component of stress on the shearing resistance is equal to that of the tangential component of stress on a tensile resistance."

From these observations, the resistance of a material to failure is a function of the internal angle of friction, so that for a ductile material subjected to a tensile stress the shearing stress occurring on a plane of maximum stress must be less than 0.7 of the applied unit stress of tension. Ductility or brittleness may be defined by a characteristic type of failure, a ductile material starting to fail by shear, a brittle material starting to fail by tension, both under tensile loading. This distinction is a novel one, and the author follows it up by the statement that, as the ratio of the composite shearing strength to the composite tensile strength is greater or less than 0.7, the material is to be regarded as brittle or ductile.

As to the ratio between the composite compressive and tensile strength, the formulas give

$$f_c = \frac{1 + \sin \phi}{1 - \sin \phi} f_t$$

With the angle of internal friction 20 deg., the compressive strength should be approximately twice the tensile strength. Experiments made to verify this ratio were not conclusive, however. The author ascribes this to flexural stresses in the compressive specimen. Offhand the conclusion that the compressive resistance is twice the tensile resistance appears preposterous. It may be, however, in view of the fact that so little is really known of true compression failures, that the ratio is correct and that more careful experimentation may confirm it.

The above ratio is identical with the one Rankine obtained for granular materials. It is possible, therefore, that soils, possessing quasi-elastic properties, have angles of internal friction constant and independent of the soil constituents.

Summing up the author's work, it appears that the angle of internal friction is constant for all elastic solids, having a value in the neighborhood of 20 deg., and that in consequence the failure type and the corresponding weak planes of that type may be predicted with reasonable accuracy, once their classification as brittle or ductile materials is determined. As an indirect conclusion, the mechanics of failure appears to be amenable to elastic theory and there is hope that more detailed attention will be paid to the characteristics of fracture rather than mere ascertainment of the breaking load.

Reservoir Loses 84% of Storage Capacity in Nine Years

Measurements of Silt Behind Old and New Austin Dams in 1900 and 1922—Stream Flow Has Ranged From 160,000 to 9 Sec.-Ft.

By T. U. TAYLOR

Dean of Engineering, University of Texas, Austin, Texas

MEASUREMENTS made in each case by the writer show that the silting up of the reservoir formed by the new dam across the Colorado River at Austin, Texas, decreased the storage capacity by 83.84 per cent in the nine years ending in the summer of 1922, compared with a decrease of 62 per cent behind the first dam in the four years ending May, 1897, and 52 per cent for the 6½ years from May, 1893, to January, 1900. The amount of water stored behind the old dam in the 2½ years between the 1897 and 1900 measurements increased due to the flushing out of silt, notably by a flood which caused a 9.8-ft. depth of water over the crest of the old dam in June, 1899. It should be noted that the river cross-sections on which capacities for 1893 are based were taken in 1893. Details of the author's measurements are given below, together with notes on various Colorado River floods and on the minimum floods on record. [For the earlier measurements, reference may be made to an article by Prof. Taylor on "The Silting Up of Lake McDonald and the Leaks in the Austin Dam," *Engineering News*, Feb. 22, 1900, p. 135. The article is accompanied by a tabular and graphical presentation of the depth of silting at twenty stations, as measured in 1900, a map of the Colorado River and a curve and formula, the latter with derivation, showing rate of silting worked out in terms of depth on 1 sq.mi. Water flowed over the crest of the old dam for the first time in May, 1893. The dam was destroyed by flood on April 7, 1900.—EDITOR.]

Silting of New Lake at Austin—The contract for the present Austin dam was let in 1911 and the dam was partly filled by the summer of 1913. In September, 1913, the lake was filled with water up to the present spillway, which is 51 ft. above the toe of the old dam—the datum usually adopted. The dam, which has not yet been accepted by the city of Austin, has been in the hands of a receiver, Guy A. Collett, since 1916. In 1918 Mr. Collett, with the consent of the federal authorities, sold the water in the lake to the rice growers in the lower countries for the purpose of irrigating thousands of acres of rice on both sides of the Colorado River. This drained the lake.

In September, 1922, the writer cross-sectioned the lake at the old stations and found the results as shown by the accompanying table and diagram. In brief, the water storage capacity of the lake in 1922 was only a sixth of what it was in 1913. Making use of the author's formula for rate of silting in terms of depth on a base of 1 sq.mi. (for derivation, see *Engineering News*, Feb. 22, 1900, p. 135), in which $h(1-x)^n$ = depth of water after n years, we have $h = 52.87$, and depth of water = 8.53. Hence $52.87(1-x)^9 = 8.53$ or $(1-x)^9 = 0.1616$. Hence $x = 0.1834$. That is, on an equal base, 18.34 per cent of silt was deposited each year on the average.

Historic Floods at Austin—The biggest floods of which we have knowledge are those of 1843, 1852, 1869,

1870, 1900 and 1913. The discharge of these floods has been estimated but no reliable measurements of any of them were made except of 1900. The following notes on these floods will be confined chiefly to that of 1869, although brief comments on some of the other floods and some general comparisons will be given.

Flood of 1869—The flood of 1869 is referred to by old settlers in Texas as the greatest in the history of the Colorado River. The writer has gone to considerable trouble to find accurate data in regard to this flood and submits herewith extracts from the diary of E. C. Bartholomew who has been a resident of Austin since 1867.

Wednesday, July 7, 1869: The Colorado River is tremendously high and causes great excitement. The people living on the bank are nearly all moving, and many houses are under water. Monroe Swisher's house across the river floated off, as well as other houses of an inferior class. Fields of cotton and corn on the river bottoms are covered with water, and the loss is immense. It has rained steadily since last Saturday night (July 3, 1869) until today. The river rose into the Davis large mill (Zilker ice house) on the bank of the river.

Saturday, July 17, 1869: We received the first Northern mail this morning in 13 days. The flood prevented the running of stages.

Capt. W. C. Walsh, another old resident whose home in 1869 was between Barton Creek and the Colorado River, states that the heavy rains began at 4 p.m. on June 27, 1869, and continued until about 3 a.m. of June 28, when the back water in Barton Creek was approximately 30 ft. deep. The rains continued through June 29 and 30, light showers alternating with heavy downpours. Rain began falling again on Saturday, July 3, and continued until the morning of July 7, when the maximum flood occurred. On the morning of July 7 the water was about 6 ft. deep at the gateway that leads to the present Barton Springs park.

The flood of 1869 is regarded as the biggest flood that ever occurred in the Colorado River, but E. C. Bartholomew distinctly questions whether the flood of 1869 was greater than the flood of April 7, 1900, that broke the Austin dam. There was a ferry across the Colorado River at the foot of Congress Ave., where the present reinforced-concrete bridge exists. Old settlers unite in stating that there was a high bluff from the present concrete bridge to the railroad bridge of the International & Great Northern Ry. This bluff was composed largely of alluvial deposits and was nearly as high as the present north bank. The flood of 1869 cut down this high bank on the south side, and eroded the plateau south of the bank for many feet.

Thus, the flood of 1869 and the flood of 1900 were passing through channels whose cross-sections were entirely different and there is no basis of comparison.

Flood of 1870—Quoting again from the diary of E. C. Bartholomew, this time under date of Monday, Oct. 17:

It rained hard all night, and when I arose this morning the river was up nearly as high as it was one year ago last July. The water carried off the pontoon bridge, and has caused great destruction on plantations below.

Studies at Webbersville of 1869 and Other Floods—Because the flood of 1869 changed the cross-section of the river at Austin, the writer made a special investigation of the floods at Webbersville on the Colorado, eighteen miles below Austin. At this place, the cross-section has remained practically constant. The village of Webbersville is situated on the north bank of the

RESULTS OF SILT SURVEY BEHIND NEW DAM AT AUSTIN, TEXAS SEPTEMBER, 1922

Station and Distance from Dam	Name	Miles	Depth of Silt as Measured in Feet			
			Mean 1913	Mean 1922	Maximum 1913	Maximum 1923
Dam		0.0	36.10	14.44	60	19.00
Bee Creek		0.2	36.57	11.33	60	16.00
Almon		1.2	29.91	6.13	57	12.20
Dry Creek		3.0	30.00	3.70	67	6.60
Bull Creek		4.0	29.43	3.60	38	6.40
Kniss		5.6	32.25	4.21	38	7.00
Devils		7.0	31.08	5.54	38	6.80
Ogarta		7.8	27.29	4.89	36	6.30
McNeill		9.3	26.83	4.70	31	6.20
Scotts		10.4	22.00	5.22	31	8.00
St. Monica		13.7	19.62	2.80	21	5.20

	Cubic Yards	Acro-Feet	Feet Depth on a Square-Mile Basis
Volume of water in 1913	54,591,680	33,745	52.87
Volume of water in 1922	8,805,280	5,456	8.53

Ratio of water volumes, 1922 to 1913 = 0.1616 or 16.16 per cent; or in the nine years from 1913 to 1922 Austin Lake has filled 83.81 per cent of its 1913 volume leaving a water volume only one-sixth that of 1913.

Colorado River, and the old settlers there were in all the floods since 1868, and the writer is able to make the following definite report:

The flood of 1869 flooded Webbersville to a depth of 9 ft. and covered the farms to the foot hills, on the north, a distance of 1 to 1½ miles. The flood of 1870 was 3 ft. deep in Webbersville, and, therefore, 6 ft. below the flood of 1869. The flood of 1900, that washed away the Austin dam, did not get out of the banks of the river at Webbersville on the north side. The flood of December, 1913, was about 1 ft. higher than the flood of 1900. Therefore, in order of magnitude, the floods stand: 1869, 1870, 1913, 1900, 1899. The writer was unable to get any data in regard to the floods of 1843 and 1852.

During the flood of 1869 all the creeks between Austin and Webbersville were at flood stages, and therefore added their volume to that that passed Austin. However, the flood of 1870 came like a thief in the night, reaching Webbersville and overflowing farm lands while the farmers were working their fields. The 1870 flood came from the upper reaches of the Colorado River.

Flood of 1899—Although no reliable measurements of any of the floods were made, except that of 1900, calculations can be made for the flood of June, 1899. The old Austin dam had a rounded crest 1,091 ft. long, and

RELATIVE DEPTHS OF SILT AND WATER BEHIND AUSTIN DAM IN SEPTEMBER, 1922

The stations are given in miles above the dam. See table for depths in feet.

we could apply Francis's weir formula to the calculation of the discharge. The coefficient in the Francis weir formula is 3.33 but it is a well-known fact that this increases as the depth increases and the writer is of the opinion that in the case of the Austin dam this coefficient was nearer 4 than 3.33. A coefficient of 4 in the Francis weir formula will give a discharge of 160,000 sec.-ft. for the flood of April 7, 1900. It is to be recalled that this flood was produced almost entirely by the rains that fell in the Canyon section, between Marble Falls and Austin. The heavy rains

began at 6 p.m. on April 6, 1900, and continued for about twelve hours steadily. At 11:20 a.m., April 7, 1900, the old Austin dam cracked, and soon portions of it were washed away.

Low Flows of Colorado—In 1910 and 1918 the Colorado River reached its very lowest flows of recorded history. In 1910 the writer measured the flow at the dam from Aug. 15 to Sept. 28 and found it to be only 21 sec.-ft. In 1918, after the water had been drawn from the lake, the whole flow of the river plowed a narrow furrow through the silt above the dam, and the channel was so narrow that it was easy to hop across it at one jump. At this time the whole discharge of the Colorado River was only 9 sec.-ft. immediately above the dam, the flow being confined to a channel about 4 ft. wide in the silt.

Shaded Topographic Maps Are Developed by Geological Survey

WITH THE RECENT production of a shaded topographic road map of the region of Washington, D. C., the United States Geological Survey has made a further step in attempts to improve the legibility of its regular topographic maps by the use of shading. A section of the Washington map is reproduced herewith, reduced to one-half the scale of the published map (Fig. 1). An example of a different style of representation, a combined contour line and shaded map, is also shown (Fig. 2).

For a number of years the survey has been experimenting with various types of shading for showing relief both by itself and in connection with contours. The combination of shading and contouring, as exemplified for the Monument Spring section in Fig. 2 herewith, is considered to be well adapted to use for regular engineering purposes. A number of sheets in West Virginia and Pennsylvania are in course of preparation, and it is intended to publish them in the near future as a means of securing an expression from users of topographic maps as to the value of this method of showing relief. If opinion is favorable, other maps in

FIG. 1—PART OF SHADED ROAD MAP OF WASHINGTON AND VICINITY

One-half actual size. A greenish gray was used for the topographic shading, red for through roads (heavy lines), black for minor roads (fine lines), and blue for water.

various parts of the United States will be produced as demand requires. The extent of the work necessarily will depend on funds available. The same remarks apply to the method of representation used for the Washington road map, in which surface contours are not considered necessary.

The Monument Spring map was prepared under the supervision of J. H. Renshawe, of the Survey, an expe-

FIG. 2—CONTOURS AND SHADING COMBINED
Part of Monument Spring quadrangle, Brewster County, Tex., reproduced one-half original size. The contours are in brown as on the ordinary topographic maps of the U. S. Geological Survey. A brown stipple is used for the topographic shading, which is so applied as to give the effect of shadow under illumination from the upper left.

rienced topographic engineer and also an artist. The shading is so applied as to produce the effect of a sculptured relief model under oblique illumination. The aim of the artist was to bring out the character and individuality of the different topographic features, so far as the limitations of the scale would permit. The map further embodies an attempt to express differences in altitude by gradation of the shading tint, dark tints being employed for low lands and lighter tints for high lands. The use of hard lines was avoided, and a soft mellow effect was sought, so as to bring out the outstanding features in correct proportion, to enable the map reader to visualize the country at a glance.

Where standard topographic contoured maps exist, the work involved in preparing the shaded copy for combining with the contouring is not costly. The shaded copy can be prepared in a few days by a trained cartographic artist at an expense of approximately \$70 for a standard topographic sheet, and the additional cost of mechanical reproduction would not exceed \$75 a sheet for the ordinary editions.

The Washington area was selected for the purpose of bringing the question of shaded road maps for regions near large cities to the attention of road users. No additional field work is involved in producing the shaded map, and no great additional cost in applying the shading and in printing. It is expected that the result will prove to meet the requirements of tourists and automobile users far better than the ordinary road maps without relief.

Where the topographic survey of a state has been completed and published maps exist, a shaded relief map on the scale 1:500,000 will be prepared. The best example of a shaded map of a state that has been completely topographically mapped is that of Ohio, and the results obtained by Mr. Renshawe on this map may be considered as a standard of what can be expected for other states as rapidly as the topographic surveys are completed.

Expressions of opinion concerning these two types of shaded maps are desired by the director of the U. S. Geological Survey.

Reclaimed Rubber Tires to Be Tested

An order for fifty tires made with various amounts of reclaimed rubber in the tread has been placed with one of the rubber companies by the U. S. Bureau of Standards. These tires, when completed, will be tested in the laboratory and also on trucks of the post office department on four different types of road, to determine the relative wear resistance of the different compounds.

Inadequate Design Causes Failure of Concrete Swimming Pool

Structure at Midland Beach Resort, Costing \$63,000, Damaged Through Collapse of Sidewall When First Filled

LACK OF adequate engineering design was apparently behind the failure, on July 3, of a reinforced-concrete swimming tank at Midland Beach, near New York City, built by the owners of the resort, and scheduled to have had its opening on July 4. The tank had been constructed hastily and was being filled with water for the first time when about half of one of the side walls pushed out, shearing off along the line where the side wall joined the floor slab. Property damage sustained through flooding was estimated at several thousand dollars.

The tank was built upon filled marsh land and was

FIG. 2—VIEW OF COLLAPSED PORTION

supported on timber piling. The structure, of rectangular shape with semi-circular ends, has a length of 200 ft. and a width of 83 ft. It was to provide for a water depth of 3 ft. at the shallow end, with the bottom sloping to provide a 11-ft. depth at the deep end. Concrete slab and side walls are about 12 in. thick.

Inspection of the tank after failure would indicate that the greatest structural weakness lay in the lack of buttressing or counterforts to resist the heavy pressure of water exerted by a filled tank. As the photographs indicate, the structure is built in such fashion that the side walls merely rested on the slab, an attempt having been made to tie slab and walls together by bent 3-in. deformed bars. There appeared little uniformity in the spacing of the bars. When the side wall fractured it failed along the top of the slab, the slab under the inside half of the wall being left clean after failure.

FIG. 3—CLOSE-UP OF REINFORCEMENT

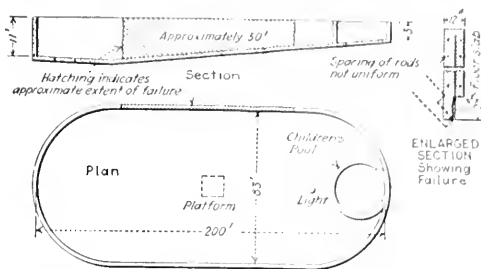

FIG. 1—PLAN OF POOL AND SECTION OF WALL

Lack of adequate design was also apparent in the failure to provide expansion joints. There was no provision for expansion longitudinally though laterally several straight cracks clear across the slab were apparent.

FIG. 4—REINFORCING CLEANED OF CONCRETE

The concrete used in the construction of the pool seemed to be run from bank run gravel and sand and no effort seems to have been made either to accurately measure it or exercise care in running the batches.

Competent advice was sought when the project was first proposed and a preliminary sketch was submitted by a reputable architectural and engineering office, but the owners for some reason did not retain the original designs although the layout was followed to a considerable extent.

The pool was built by the Midland Beach Co., at a cost of \$63,000, James C. Hinchliffe of Paterson, N. J., representing the owners. It is practically a dead loss as there are indications of failure in other parts of the construction.

Interchange in Formulas

An error in checking the formulas in the article "Trapezoidal Portal and Eccentric Heel Joint of Truss," by Camillo Weiss, printed on page 339 of the issue of August 30, interchanged the formula for moments M_A and M_B in two cases. The formulas for M_A and M_B below the middle of the first column, and the corresponding simplified formulas near the top of the second column, should have the right hand expressions interchanged, or they can be made to read correctly by writing M_B for M_A and vice versa. The formulas as still further simplified near the middle of the second column are given correctly in the printed text.

Two Precast Concrete Bridges on Lackawanna R.R.

One Carrying Railroad at Millburn, N. J., Made Up of Heavy Slabs Replaced Under Traffic Lighter Steel Structure—Other 48-Ft. Footbridge Over Three-Track Right-of-Way

By M. HIRSCHTHAL

Concrete Engineer, Delaware, Lackawanna and Western R.R.,
Hoboken, N. J.

IN THE design of railroad structures replacing those in use the main consideration is to cause a minimum disturbance of traffic. This factor frequently far out-balances economy in the design of the structure itself, for the difference in the cost of track work or temporary construction for two different types of design may constitute a large percentage of the total cost of construction. To eliminate interference with traffic and

forms and permitting the removal of the brackets, thus reducing the loads on the girders, which were then being overstressed by the increase in locomotive loadings. These loadings however continued to increase and it became necessary to replace the structure by one more modern to meet future requirements. In 1921 plans were prepared for such a structure. The first type to be considered was one similar to that to be replaced, with the exception that the sidewalk spans were to be of concrete and the main bridge floor solid, as in the section in Fig. 2. The girders were to be supported on concrete arched piers encasing the then present columns, which construction also carried the sidewalk slab and necessitated the through girder construction over the roadway only. This scheme was discarded for one which dispensed with the use of the through girders, consisting of a floor of 30-in. Bethlehem girder beams spanning the roadway and spaced about 2 ft. centers, filled solid with concrete to form a 36-in. solid floor (Fig. 3).

Type Selected—The final variation was the substitution of reinforcing steel for the Bethlehem girders, which could only be accomplished for that thickness of slab by the use of compressive reinforcement, thus making the structure a reinforced-concrete bridge. The substitution reduced the weight of the slabs sufficiently for the handling of larger units as precast slabs.

The clear roadway span which is maintained in the present design is 30 ft. measured at right angles to the center line of street which makes an angle of 79 deg. with the tangent to the center line of tracks and result-

yet obviate the necessity of temporary construction, precast reinforced-concrete members have often been designed but with limitation as to spans, loads, and type of structures. Methods to extend these limitations to the point of almost removing them have recently been used with highly satisfactory results on the Lackawanna R.R. in two interesting examples of precast reinforced-concrete bridge work. The two structures to be described are the extremes of bridge work, the one a railroad bridge to withstand locomotive loadings as an undercrossing, the other an overhead footbridge.

Millburn Undercrossing Requirements—The undercrossing is a replacement of a structural steel bridge at Main St., Millburn, N. J., on the main line of the Morris & Essex Division, subject to the heavy suburban traffic between Morristown and Hoboken. In 1894 this structural steel bridge, an unusual type, was built to provide for two tracks and station platforms, the latter by means of brackets cantilevered from the fascia girders which were each spaced 14 ft. 6 in. c. to c. from the center girder. All of these were through girders supported on steel columns (braced by latticed struts) along the curb lines and masonry abutments along the street lines. The floor beams, spaced 5 ft. 11 in. c. to c. were supported on the lower flanges of the girders while the stringers consisting of two channels back to back were framed into the floorbeams at different levels to take care of the superelevation required for the 4 deg. curvature of track compensated. The ties were placed on the stringers to form an open floor leaving the roadway span unprotected. The sidewalks, however, were protected by wooden canopies spanning from the abutment to a channel connected with the columns. Fig. 1 shows the old structure.

Some ten years later the station was moved about a thousand feet further east, dispensing with the plat-

FIGS. 2 AND 3—TWO STUDIES OF PROPOSED NEW BRIDGE, BOTH REJECTED

Both designs incase old steel supports in concrete. Fig. 2 shows new steel girder bridge with 20-in. floorbeams and solid concrete floor, with reinforced-concrete spans over sidewalks. Fig. 3 substitutes solid concrete main span, of Bethlehem beams incased in concrete.

ing in a skew span of 30 ft. 7 in. The track centers are also maintained at 14 ft. 6 in., requiring two 7 ft. 3-in. slabs to carry the load of one track (Fig. 4).

The various portions of the structure were designed to carry an E-65 engine loading. For this condition of loading a slab simply supported, reinforced for tension and shear only, would have required a depth of 49 in.

strut angles and reinforcing bars to transfer their loads to the concrete columns encasing the old ones of steel. The masonry footings were found to be sufficiently strong to carry the new loads, except that those at the ends were increased to provide for future third tracking. The pier is so designed that an addition can be made to accommodate the installation of a third track.

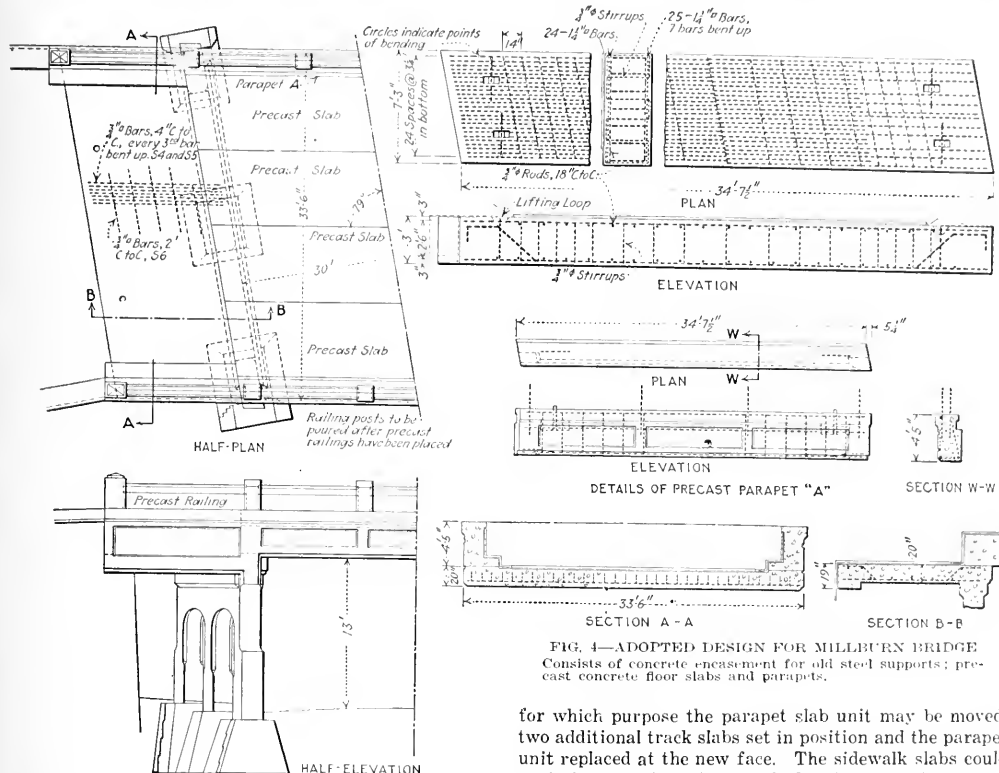

FIG. 4—ADOPTED DESIGN FOR MILLBURN BRIDGE
Consists of concrete encasement for old steel supports; pre-cast concrete floor slabs and parapets.

for the roadway span. Since the depth was limited to 36 in. the deficiency in the compressive resistance of the concrete for the latter depth was compensated for by the use of compressive reinforcement in the upper plane of the slab, with the required additional tensile reinforcement in the lower. Twenty-four 1½-in. square bars were required for compression and twenty-five for tension to resist the maximum moment at the center of span. After the quarter-point of the span was passed, the steel was reduced to take the moment at that point. Two lifting loops of 1½-in. round rods were imbedded at each end of the slab for handling both in loading on the cars and for setting in place. To provide for the maximum shearing stresses seven of the tension bars were bent up near the supports and stirrups of ¾-in. rounds were spaced as shown. The parapet slabs for the main span are of sufficient depth to require no compressive reinforcement to resist moments due to the load they were designed for. The parapet slabs for the sidewalk spans were precast as a convenience in construction.

The piers were designed to take the maximum live-load reaction together with that of the dead-load and impact, the arched girders being reinforced both by the

for which purpose the parapet slab unit may be moved, two additional track slabs set in position and the parapet unit replaced at the new face. The sidewalk slabs could again be poured in place, with the pier extension.

CASTING METHODS—The precast units were cast in the yard of the shops at Kingsland, N. J., which is on the Boonton Branch. The forms were erected on a platform, the reinforcing steel was secured in position and the 1:2:4 machine-mixed gravel concrete poured. Two sets of forms were used and one track slab and one main parapet slab were poured in one operation. The concrete was cured in the open air and flushed twice a day for two weeks. All the slabs were treated in this manner and were cured at least thirty days before they were loaded on the cars for shipment to their destination. The weight of one track slab is 57 tons.

In order to expedite the completion of the work the precast slabs while still in the yard were waterproofed and a protection coat was provided to within lapping distance of each edge, the cloth extending a lap beyond the edge and being bent back pending erection, after which the cloth was bent back into position and the protection coat placed. The waterproofing for all the work consists of two plies of asphalt-saturated cotton cloth laid in asphalt and protected by 2½-in. thicknesses of asphalt mastic.

The piers and sidewalk slabs however were poured

FIG. 5—METHOD OF PLACING PRECAST SLABS AT MILLBURN BRIDGE

in place without disturbing traffic either of the railroad or of the thoroughfare. The masonry of the abutments was removed to a point below the proposed level of the bottom of the sidewalk slab, the structural steel girders were blocked up a few inches to clear the sidewalk slabs, while the struts on the south half of the bridge, being too low, were cut off and replaced at the higher elevation as shown in Fig. 4. The forms were then built around the columns and struts as well as for the sidewalk slabs, the reinforcement placed in position and the concrete poured, each pier with its adjacent sidewalk slab comprising one operation, without interfering with traffic. These were allowed to cure for a month before the precast units were placed in position.

Erecting Millburn Bridge—The process of erection of these slabs was as follows: The precast units were loaded on flat cars at Kingsland, N. J., and transported to the site of the work at Millburn, N. J. It was planned to complete this erection and the raising of the track between the passage of the westbound train at 11:33 p.m. Sunday, and that of the eastbound at 4:11 Monday morning, or within a little more than four and one-half hours. It was decided to install the westbound track first because of the superelevation, therefore this track was cut east and west of the limits of the bridge while a work train was located on the eastbound track, as shown in Fig. 5. The work train consisted of the cars on which the slabs were loaded, a 150-ton wrecking crane, empty cars and a 35-ton crane. The floorbeams of the westbound track were cut free from the center girder, and, together with their fascia girders, each sidewalk span was lifted by the respective cranes into the empty cars which were then drilled out of the way

and replaced by two other empty cars, with the cranes located on either side so that together they could lift the main span (fascia girder and floor beams) and load it onto the cars. The smaller crane was then drilled into the switch while the remainder of the train was manipulated so that the wrecker was located east of the cars containing the track slabs, after which the smaller crane was again shifted into position west of the cars, enabling both cranes to handle the units which were then placed in position clear of the center girder and tracks blocked up to new level 2 ft. 6 in. above the old.

It then became necessary to raise and ballast the track for a total distance of 1,800 ft. on both sides of the bridge, precluding the possibility of completing the eastbound track side of the bridge that night. The tracks at the bridge were then blocked up to permit of the completion of the waterproofing. Two nights later the work was resumed. The eastbound track was cut at both ends of the bridge, the wrecker located on the east end and the crane on the west while the train was so located that the empty cars were on the newly set span of the westbound track. The cranes then lifted the old steel sidewalk spans into the empty cars which were drilled out of the way, replaced by the other two empty cars into which was loaded the main steel span and these also were drilled out of the way. The cars containing the slabs were then located in position and the slabs, handled by the two cranes, were set in place and all of them aligned, the track was graded and ballasted on both sides of the bridge at which they were blocked up, traffic was resumed on both tracks and the waterproofing completed between trains. After all this the ballast was placed. The bush-hammering was then completed and a concrete balustrade cast in place, resulting in a structure as pleasing as one built in place.

East Orange Footbridge—The other example is a footbridge to replace one of structural steel, for Maple Ave., East Orange, in connection with the East Orange improvement described in *Engineering News-Record*, Nov. 9, 1922, p. 778.

This bridge consists of piers cast in place on top of the continuous retaining walls, which were built in connection with the depression at this point, the girders together with the slab spanning between them constituting the precast section. The stairways leading from the bridge at either end, like the piers, were built in place.

The piers carrying the footbridge are supported on the retaining walls and held in place by means of five 1-in. square bars imbedded in both walls and piers for a length of 3 ft. 6 in. in each, or about 40 diameters. The piers are 1 ft. 9 in. thick and somewhat more than

FIG. 6—THE FINISHED PRECAST CONCRETE BRIDGE AT MILLBURN

The fascia girders 4 ft. 3 in. high result in 3 ft. 9 in. depth of railing, but this does not provide the required compressive resistance for the span, necessitating the use of compressive steel reinforcement, consisting of six 3-in. square bars as shown in the cross-section. The

FIG. 9—THE MAPLE AVE. PRECAST BRIDGE IN PLACE

The supporting piers have been built up from the retaining walls alongside the cut; the approach stairways have not been put in position.

tensile reinforcement consists of ten $\frac{3}{4}$ -in. square bars two of which are bent up to resist diagonal tension in addition to the vertical stirrups of $\frac{1}{2}$ -in. square section spaced 2 ft. 6 in. on centers throughout the length of the girders.

This footbridge was also cast in the yard adjoining the Kingsland shops. The forms were erected on a platform, reinforcement was set in place and concrete of 1:2:4 proportion with broken stone as the coarse aggregate was poured, of course, in one operation (the volume amounting to less than 30 cu.yd.). After the forms had been removed and concrete sufficiently hardened the panels formed by the indentations were bush-hammered, and the bridge was ready for transportation to the site of the work.

To insure against any damage to the bridge in the various operations incident to final erection and to facilitate handling, a combination of spreader and cradle was devised, to encircle the structure at points adjacent to the curved sections near each end. Each of these cradles consisted of a pair of 15-in. I-beams side by side, both under the soffit of the slab and above the tops of the girders. They projected beyond the structure sufficiently to permit bolting them together at both top and bottom flanges by plates 1 in. thick and 15 in. square at each end. At the center of this spreader there was provided a pin of 3 $\frac{1}{2}$ in. diameter held in place at the underside of the I-beams by means of a 1-in. plate bent to the radius of the pin, the flat portions being bolted securely to the two I-beams. This pin was connected with a 3-in. eyebolt ending in a loop to engage the hook of the crane. Fig. 8 shows these details quite plainly.

In preparation for setting the bridge on the flat car used for this purpose, a timber grillage was built near each end to a height sufficient to keep the curved ends off the floor of the car. Two cranes, one at each end of the bridge, each engaged a lifting loop, raised the bridge from its platform and set it on the flat car in proper position. The train including the cranes then moved to East Orange via the Bergen Hill Tunnel at Jersey City. The bridge was set on its supports by the two cranes, in the same way it was loaded on the cars in the hour between 1 and 2 a.m. after the last westbound suburban train had passed.

In the design of both these structures the unit stresses, similar to all other work on the line, were

650 lb. per square inch for concrete in compression, 16,000 lb. per square inch for steel in tension and 100 lb. for adhesion between steel and concrete; the stress in the compressive reinforcement is of course much below ordinary allowable limits, being fifteen times that of the concrete at the section of its embedment or in the neighborhood of 7,500 lb. per square inch. The weight of the precast bridge is 57 tons.

Oregon Short Line R.R. Improves Idaho Division

Relocation, Grade Reduction and Double Tracking
for Tonnage Trains—Pusher Sections
Reduced—Construction Work

DOUBLE TRACKING and grade reduction on pusher grades of the Oregon Short Line R.R. near Glens Ferry, Idaho, are being carried out to effect material improvements in operating conditions on the two freight districts of the Idaho Division, extending between Pocatello, Idaho, and Huntington, Ore., a distance of 326 miles. Except for the two pusher sections of 2 and 1.72 per cent grade these districts have very favorable grades. The work includes a 26-mile stretch of double tracking between King Hill and Reverse, two sections of relocation of the second track and the improvement of the freight yard and engine terminal at Glens Ferry, which is the intermediate district point. Between Pocatello and Huntington the line is equipped with block signals.

From the general and detail plans and profiles, Figs. 1 and 2, it will be seen that Glens Ferry, the district terminal for freight runs, lies in a deep sag in the grade line. From it the maximum ascending grades are 1.72 per cent eastbound and 2 per cent westbound. Elsewhere on the division the ruling grades are 0.5 per cent except for about 102 miles between Glens Ferry and Minidoka, where the ruling grade is 0.65 per cent for eastbound traffic on both the main line and the North Side branch (see Fig. 1). All permanent improvements on the division are being made to conform to these ruling grades.

Grade Reduction—For several years the limitations imposed by the heavy grades east and west of Glens Ferry, involving the use of pusher engines, have hampered the handling of traffic and the difficulty has been increased by lack of adequate yard facilities at this freight district point. As a result, the capacity of the single-track main line has been overtaxed during seasons of heavy business.

Extensive surveys for relocation have shown that to reduce these heavy grades to the ruling grades elsewhere on the two districts would involve prohibitive cost of construction. It has been determined therefore to retain the short pusher sections from King Hill to Ticeska on the east and from Hammett to Reverse on the west (see Fig. 2) but to reduce their grades to such an extent as to facilitate the handling of standard tonnage trains.

At present, the ruling grade eastbound from King Hill east to Ticeska is 1.72 per cent, but the second track will be constructed in part on a new location with a maximum grade of 1.5 per cent at a cost no greater than that of double tracking on the present location. The diversion will be about a mile in length and at a maximum distance of 450 ft. from the present main line. This

improvement will not involve any material increase in distance. With this reduced grade the standard 2,200-ton train load can be handled eastward from Glens Ferry to Minidoka (ruling grade 0.65 per cent) with the assistance of a pusher engine of the same tractive effort as the road engine between King Hill and Ticeska, a distance of only six miles. At Minidoka trains may be filled out to the 2,600-ton standard rating for the ruling grade of 0.5 per cent eastbound to Pocatello, the branch line feeders from the south into Minidoka furnishing ample tonnage for this purpose.

Relocation and Double Tracking—Since prohibitive cost also prevents the reduction of the westbound maximum grade of 2 per cent to the ruling grade of 0.5 per cent, extensive surveys were made to determine the best location for a new westbound second track on a grade which would fit in with the use of pusher engines. These surveys resulted in developing a line which has a maximum grade of 1.45 per cent, shortens the distance by two miles, has a maximum curve of 3 deg. instead of 5 deg. and saves 54 deg. of total curvature. The saving in distance was secured by taking advantage of the slack grade between Hammett and Reverse and starting the ascent about one mile west of Hammett. This location was adopted for a new double-track section, with abandonment of the original line.

Heavy grading is involved by this new double-track diversion, although it has no bridges and except for one 10-ft. arch span the culverts are light. Owing to the cost of earthwork this improvement was not undertaken until the increasing traffic warranted the expense. Some of the grading quantities are noted on the profile, Fig. 3. In spite of the additional cost of constructing the second track on the new location, it is estimated that this improvement will result in high economy in operating expenses due to the saving in distance, the saving in first cost and operating expenses of interlocking plants and the preservation of right-hand operation of trains on double track. All towns and business in the district involved can be served as well by the new line as the old line.

With the completion of the work described above, in addition to the 15½ miles of double tracking between King Hill and Bliss, and the ballasting and laying of

FIG. 1—OREGON SHORT LINE R.R. IN IDAHO

heavy rail on the North Side Branch (Fig. 1), the Oregon Short Line R.R. will have a continuous second track from Minidoka to Reverse, 123 miles. On the new work and in relaying the present track, 100-lb. rails of the A.R.A. section are used, with gravel ballast 15 in. deep under the ties.

Double tracking now under way covers the stretch between King Hill and Reverse, 26 miles. Work was started in June, 1922, on the section between King Hill and Hammett, and in November on the section between Hammett and Reverse. About eight miles from King Hill to Glens Ferry was put in operation on Nov. 16 and the next stretch to Hammett was put in operation on Dec. 30, 1922. Since the line change between Hammett and Reverse, nine miles, involves heavy grading, this portion probably will not be completed until near the end of 1923.

Freight Yards and Engine Terminal—Two tandem freight yards for eastbound and westbound movements have been laid out at Glens Ferry and between them is the engine terminal. At this point the two main tracks were laid on opposite sides of the 200-ft. right-

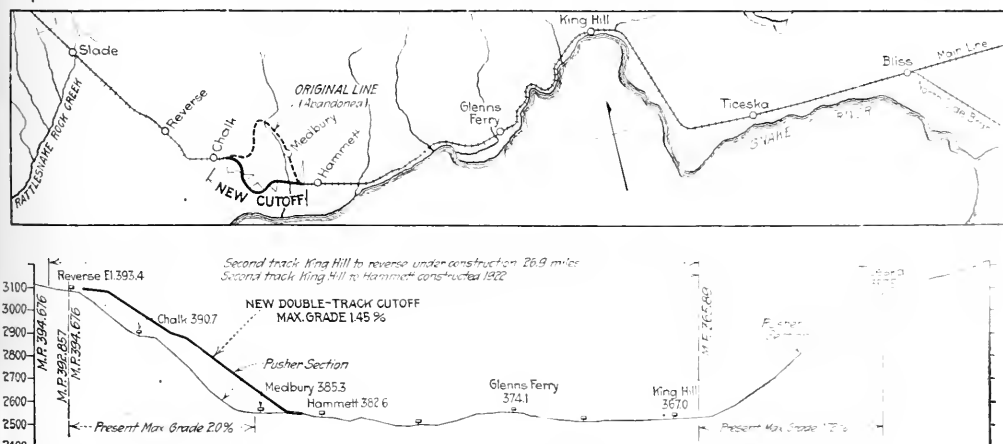

FIG. 2—DOUBLE TRACKING AND GRADE REDUCTION BETWEEN KING HILL AND REVERSE

of-way in order to permit ample development for the yard tracks and locomotive facilities. Daily freight traffic at this point averages 35 trains inbound and 35 outbound. Many of these are run through as solid trains, except for the change of engines and crews and the switching out of occasional bad-order cars. These yards are arranged for flat switching. In the ladder tracks No. 9 frogs are used, but the turnouts from main tracks have No. 10 frogs.

At the engine terminal a 100-ft. truss turntable serves a 17-stall roundhouse of brick and concrete. The

necessary to handle practically all construction operations without use of the main track. Fills were made by dumping from framed trestles having a maximum length of $\frac{1}{2}$ mile and a maximum height of 50 ft.

On the four-mile diversion west of Hammett (see Fig. 3), the total yardage will be about 1,204,000 cu.yd., averaging 300,000 cu.yd. per mile in embankment. All of this material will be hauled from cuts, with the exception of about 300,000 cu.yd. from borrow pits. In the first mile west of Hammett a heavy fill of 848,700 cu.yd. will be built with material from cuts, a large part of this coming from one cut $3\frac{1}{2}$ miles distant. The embankment will be about 3,500 ft. long with a maximum height of 75 ft.

For handling packed sand in horizontal strata, which is the material encountered between Hammett and Chalk Siding, the contractor's price for excavation covers all grading and placing without classification or allowance for haul. Other grading between Chalk Siding and Reverse will be done under the Oregon Short

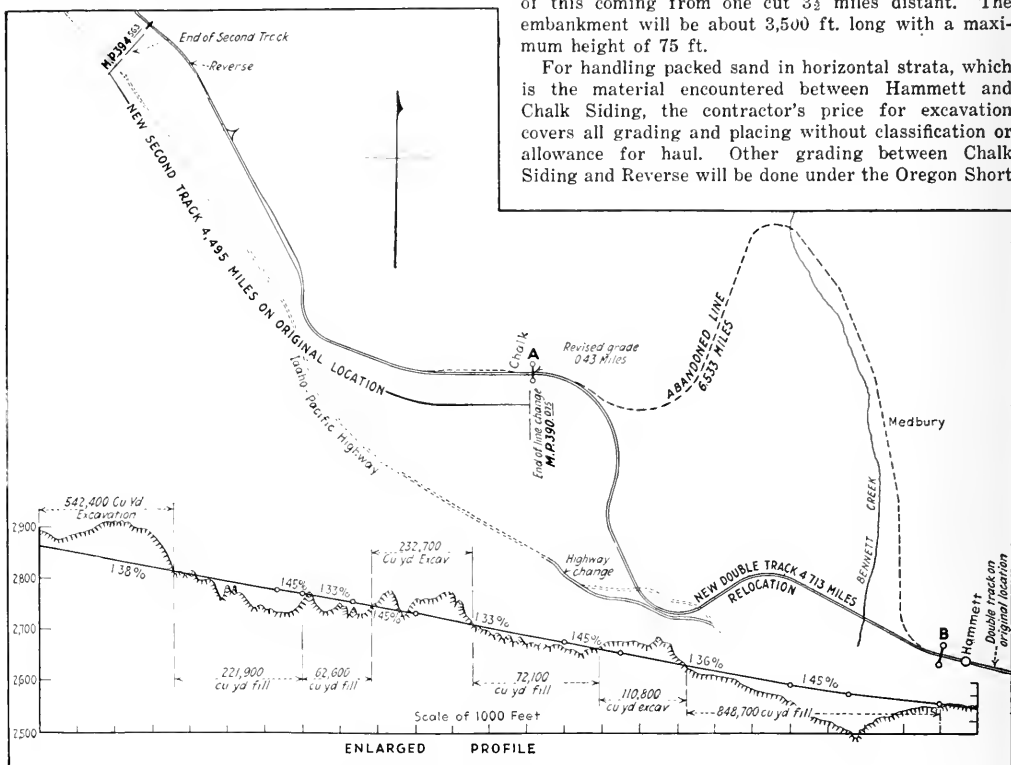

FIG. 3—PLAN AND PROFILE OF RELOCATION ON IDAHO DIVISION

ashpit is of the depressed-track type, with ashes shoveled by hand from the pit into cars on the depressed track. A new coaling station is to be built, having a bin of 650 tons storage capacity.

Construction Methods and Plant—On this improvement work the grading outfit included five steam shovels with $2\frac{1}{2}$ -yd. buckets and one dragline excavator with 5-yd. bucket and 50-ft. boom. Teams and Fresno scrapers were used also on the lighter portions of the work. Dump wagons served the dragline machine, which was used in one large cut. Both standard-gage and narrow-gage equipment served the steam shovels in cuts and in borrow pit excavation. Standard-gage side-dump cars of 12 cu.yd. capacity were used, while the 3-ft. gage equipment comprised 12-ton locomotives handling trains of ten 3- and 4-yd. dump cars. The haul was from 1,000 ft. to 18,000 ft. but on account of the heavy traffic on the existing single-track main line it was

Line R.R. specifications, which provide classification for earth, loose rock, solid rock and lava rock, with 400 ft. free haul. Fills are required to be made with 10 per cent of the cross-section added for shrinkage.

Grading is being done by the Utah Construction Co., Ogden, Utah, and the new buildings for the engine terminal are being built by C. I. Anderson, Salt Lake City. The moving of stations and other small buildings at King Hill and Glens Ferry was done by A. D. Moodie, Portland, Ore. All track and bridge work is being done by railway forces. A labor shortage from July 1 to Nov. 1 slowed up progress.

This improvement work is being carried out under the direction of R. L. Huntley, chief engineer of the Union Pacific System, and W. R. Armstrong, assistant chief engineer in charge of the Oregon Short Line R.R., with J. P. Elliott as assistant engineer in resident charge of the work.

Overlooked Items in Estimating Road Work

By C. S. HILL

Associate Editor Engineering News-Record

Factors Affecting Costs Whose Neglect or Improper Evaluation
in Estimating Turn Theoretical Profits Into Practical Losses

WHEN ESTIMATES are too low it is usually because either (1) all the items of cost are not considered or (2) some or all of the costs are not correctly evaluated or because both errors are committed. There probably never will be found a way of determining beforehand all the contingencies that affect cost, and there is even less chance of making a uniform and always correct appraisal of the sum that every contingency adds to cost. There must be always some guessing in setting prices for construction but that does not warrant wild and free speculation.

Qualifications for making correct estimates cannot be transmitted by gift. Neither is it possible to reduce estimating practice to a code. Judgment is a leading qualification which cannot be passed on by word, and conditions vary too much to be capable of expression in standard forms. Without, them, presuming to present a complete method of estimating—there being no such thing—it is possible to name some, perhaps a majority, of the factors influencing costs which are frequently overlooked in making estimates.

If a contractor would avoid overlooking important items entering into a bid, he must exercise, in its preparation, the same degree of industry and intelligence that he is willing and expects to exercise after the contract is awarded him. He should not overlook the fact that in estimating, "A little learning is a dangerous thing." It is unwise to accept the judgment of scantily experienced people on matters of vital concern in connection with his estimate. Also it is unwise to place too much reliance on the infallibility of the estimate made by the engineer in charge of the work, or, perhaps, any reliance at all on the estimates sometimes tendered by interested vendors. It is also well to avoid being influenced by figures which may have been submitted by other bidders on similar work at previous lettings. Costs of other contractors may be determined by factors one is incapable of measuring, with the information at his disposal; or possibly incapable of duplicating even under similar conditions, with his organization. A conservative policy to follow in estimating is to be unmindful of others who may be bidding and thereby avoid any possibility of allowing oneself to be influenced by what another may bid.

General Factors—An important consideration frequently overlooked by bidders is the adding of a percentage to their bids to cover the probability of having to assume many elements of risk and uncertainty, such as Acts of God, delays and suspensions of work by owners, unusual increase or decrease in contract quantities, absence of means for legal redress for inequities or arbitrary decisions. By the unilateral form of contract under which one is generally compelled to bid, the contractor may be penalized for one or all of the above contingencies. So long as this form of contract persists, it is imperative that bidders should protect them-

selves by adding to their estimated costs a proper percentage to cover probable occurrence of the above factors. No conservative business concern should assume risks without underwriting them. In one state, it was estimated in recent years, by a committee of representative contractors and engineers, that at least 15 per cent should be added to estimated costs to cover risks embraced in the form of contract in use.

Another general factor which should not be overlooked is, a decision in advance of bidding as to proper sequence of operations and the most satisfactory and economical equipment for performing them. Such a study may have great influence in reducing the volume of labor required or in increasing the amount of machinery.

With the heavy advances in freight rates, in recent years, and the constantly increasing tendency to substitute machinery for labor in road building, freight on plant has become a formidable item of expense on almost every road contract. With a scarcity of labor and the resulting unrest in its ranks, losses due to transportation advanced often assume serious proportions and should be carefully approximated. The total cost of such items as leases, rentals, camps, warehouses, traveling expenses, legal expenses, demurrage charges, telephone and telegraph bills, compensation, fire and public liability insurance and interest charges, is impressive and none of these items should be overlooked. In estimating interest charges, thought should be given to probability of delay in payment either on monthly or final estimates and also to whether or not allowances will be made for materials stocked on the work.

With the increasing size of road contracts and the growing practice of letting contracts throughout the year, increasing volumes of work have to be carried over the winter into a second season. The additional cost is an important estimate item. Again, in using previous costs, consideration must be given to whether these costs were achieved under the direction of a more competent superintendent and a more efficient organization than is likely to be available for the work in hand. Other items which have to be considered are soil and topography, right-of-way, and structural obstacles in their relation to wet weather, transportation and the probable duration of the working season for the locality.

The probable character and ability of engineers and inspectors should not be overlooked. In a particular state highway department, one will often find considerable variation in this matter and a consequent reaction on costs. If there are many engineering complications on a contract, one may encounter considerable delay and expense if the engineer is inexperienced, procrastinating or too busily engaged with other contracts to give one's problems prompt and conclusive attention.

It is well, first, last and always, to remember that there is as much in conditions as there is in prices. Successful estimating is as often the result of one's skill as a prophet as it is a matter of his industry.

Labor—A common oversight in estimating is the careful appraisal for the period of operation of the supply of labor and, as determined by this supply, the trend of wages. Last year road contractors who put in early-season bids, underestimated the season's average rate of wages. One wonders if they have not done so again this year. It is true indeed that wages and labor supply are hard to foretell, but the wise bidder will make some attempt at a valuation of both.

Some of the questions to which answers need to be secured are: Is there a local supply of labor? Is this supply normally consumed later in the season? Will there be other local construction operations to compete? Is the labor resident or transient? Are there nearby large cities to draft labor, to reflect quickly wage changes, to magnify union influences and to encourage unsteadiness and turnover? Are there living accommodations for imported labor? Finally the general market for construction labor has to be taken into account. It is to be noted again that it is the *average* wage rate for the period of the operation that the estimator needs to know.

Experience and training are other factors in the labor problem by which costs are affected and, therefore, prices must be determined. Is the work to be done with an old experienced organization, or by a new organization created for the operation? The latter circumstance will increase the labor cost by a material percentage, particularly in the early stages of the work, (1) because the untrained crew will be longer in getting the outfit ready and squared to estimate-earning work and (2) because it will turn out smaller volumes until it becomes trained.

It should be borne in mind that, in a rising labor market, labor costs always increase in greater proportion than do wages, due to decreased efficiency of production. Tables kept by one contractor last year showed that, for every 10 per cent increase in wages, there was an increase of 16 per cent in the labor cost of production. It will be immediately apparent that this is a factor of vital significance to estimators and failure properly to evaluate it has made unprofitable many contracts taken on an apparently profitable basis. An additional factor, difficult of even approximation and, oftentimes, entirely overlooked, is the expense resulting from labor turnover in those years when there is a scarcity of labor and an almost constant necessity of breaking in "green" men in place of experienced ones. While hard to estimate, this may be a prolific source of expense. On one road contract last year, where the average working force was less than 100 men, more than 800 men were actually employed during the working season. Indirect or overhead labor, such as superintendence, office force, unloading, repairing, setting up, moving and removing equipment, is an item of expense easily underestimated, particularly where there is any possibility of failure to complete work with the time estimated.

Transportation—The old habit of expecting railway transportation to be adequate has, in the last few years, been pretty well beaten out of contractors. Embargoes, car shortages, strikes and other influences of general operation curtailing railway service are being discounted. Local drawbacks are more commonly overlooked. This is unfortunate because these are the ones which it is most within the power of the contractor to appraise and overcome.

Some of the contingencies in transportation to be regarded are whether service is by a main or secondary or branch line; what the frequency and time of train movements are; whether the direction of light train movements is that in which job shipments will come; whether the local car and general freight-handling facilities are good; what additional sidings, unloading spaces and car moving equipment will be required; what the road conditions are to and from unloading points and railway distances to supply points.

Train movements are of vital concern. Carload shipments must be by regular trains and the frequency of these and when they come in determine arrangements which have to be made for receiving shipments. Generally secondary line service is best if the freight originates on the line; main lines are more apt to be crowded with higher classification freight which will receive preference, and branch lines have fewer available trains. Also generally better service is had if the shipments are in the same direction as light freight movement. The local carload freight handling facilities determine what the contractor will have to provide in the way of sidings and how much shunting and shifting he will have to do. Generally lack of means of handling shipments increases both the cost of receiving service and the inevitable demurrage charges.

Roads are another factor in transportation costs that frequently are overlooked with disastrous consequences. Not only the roads for getting materials to the operations of construction but roads to and about the unloading yards and even to the town and railway station where supplies are got and small shipments arrive have to be considered for all conditions of weather and with the loads to be hauled in mind. Underestimated costs properly to maintain roads serving the job have cut the paper profits of many a highway contract.

Materials—Taking the lowest bid for materials as a basis for estimating without knowing whether the dealer or producer can deliver as fast in the amounts wanted as is required and whether the material is of a quality that will be accepted by the inspector is a common error. Quality and regular delivery are the paramount considerations and the price should be fixed on this basis. On materials not bought on contract, a price has to be estimated with due regard for the probable trend of the market. Other items are the cost of storing, shifting and rehandling materials, and waste incident to these operations as well as to damage and accidental loss which cannot be avoided. Failure to provide waste insurance in the estimated prices of materials cuts into profits. It is pertinent to note here that adverse railroad conditions in recent years have strikingly demonstrated that stocking and rehandling large quantities of materials is less expensive than delays often resulting from lack of materials. Liberal allowance should always be made for stockpiling and rehandling expense which average experience indicates to be necessary for an uninterrupted flow of paving material to the job at all times.

Supplies—Proper consideration is not often given to the cost of supplies. Individually the items may be insignificant but the total always runs into a considerable sum. An item easily overlooked here is the cost of repair parts and shop work for machinery, which will vary greatly according to age and condition of equipment. Besides the actual prices paid and the amounts

required, there are freight and express charges and delivery expense for all supplies. The cost of handling numerous small quantities and articles is a larger amount than one imagines until the figures are totalled. Any contractor will do well to prepare lists of supplies, for particular types of roads, using previous job records, and work out approximate figures for shipping and handling costs. Going over such details and figures, when an estimate is being made up, will often save an under-allowance for supplies.

Plant and Tools—It appears to be a natural habit to underestimate these items of expense. Extra gangs, changes in plans and misjudgment in co-ordinating operations are contingencies that must be anticipated and all of which add to the stock of equipment and tools required. As an example, the failure of a planned water supply may require additional development, pumping outfit and pipe line. Plant depreciation is one of the most troublesome items for the estimator and one on which there is room for considerable divergency of view. Where a contractor has been forced to make large purchases and immediately encounters a falling market, it accumulates added significance. Under these conditions, the first cost of a heavy plant investment might drop 33½ per cent during one season's operations. Assuming such a condition, the owner would be faced with a loss of one-third the value of his equipment, plus the depreciation upon the remaining two-thirds. Under these conditions, and under the small margin of profit on which highway work is bid, an otherwise profitable commitment might be thus turned into an unprofitable one.

Excavation Costs—Failure to study all excavation involved, in the field, and work out in advance of bidding an approximate classification of materials to be handled in grading foundations, ditches, borrow pits, shoulders, dressing slopes, refilling rock-breakage in cuts, etc., as well as the relative cost of each type of work is common. Because of the difficulty and expense necessary properly to keep such costs, we find not only contractors' records, but the actual technical literature in existence on this particular subject, very barren. After all care and skill have been exhausted, however, we are still forced to admit that any estimate upon road excavation will, doubtless, vary more widely proportionately from the actual costs experienced than the estimate upon any other item in a highway contract. Under these conditions, one might think that contractors would proceed with more caution and be less inclined to flirt with the danger line, in bidding on this item, than on any other item of a contract, but no such impression can be justified by the history of costs in recent years.

It is quite common not to estimate even approximately on the amount of fence moving, sod clearing, scarifying and other items which may be included in the excavation price, not to approximate average length of haul or overhaul on excavation and borrow, not to recognize that, on most road construction in cuts, it is impracticable not to excavate the shoulders of the road and then replace them without payment for either operation.

Other Contract Item Costs—In the same category with these oversights in estimating excavation is the common failure, in bidding on masonry work, to recognize the great variation in the unit costs of labor and other expenses, as between bridges, walls and other heavy masonry and pipe head walls, curbing, gutters, etc. Such items as head walls, bridge parapets, curbing

and gutters will be comparatively much more expensive than other heavier types of masonry, not only in labor, but also in waste of material. As an instance of this, on a road built in 1920, the cost of rubbing down head walls, with labor at \$4.50 per day, was found to be 30c. per cubic yard of concrete.

In fixing prices on varying sizes of curbing, gutters, etc., many bidders apparently fail to recognize the basic fact that the smaller the volume of concrete, or other material, per linear foot, the greater will be the unit cost of handling and placing a cubic yard; of handling forms, finishing, protecting, moving equipment; of ratio of material waste. The same is true of excavation prices in that they sometimes appear to indicate a premise that excavation for tile drain, curbing and other small items can be done as cheaply as grading where quantities are large.

The cost of materials for pavements is usually a large part of the cost of a modern highway, hence the importance of adding to one's bid an ample percentage to cover waste and the labor expense in handling that waste. In some instances, highway departments and inspectors still insist upon the right to reject materials after unloading from railroad cars, without compensation to the contractor even though the burden may properly rest upon the material producer. As producers almost invariably refuse to accept responsibility for paving material condemned after unloading, it is proper to add a percentage for protection against this contingency where it is likely to be encountered. In some localities, it is essential for a bidder to protect himself against arbitrary decisions as to proportions of paving and other materials. In one state, in recent years, it was estimated that an arbitrary decision requiring contractors to give compacted measure on cement and accept loose, unshaken measure on aggregates, cost the contractors over \$100,000 in a single working season. Recognition of this hardship was refused and no legal means of redress was possible under the form of contract in vogue.

Care should be exercised not to overlook figuring shrinkage as between loose measure and solid measure in the construction of sub-base, broken stone base and other foundation courses.

Conclusion—In conclusion, it may be said that there is no "royal road" either to the best estimating or to preventing the disappearance of paper profits. To the close student of the subject, however, this fundamental thought should always suggest itself: *No matter how many uncertainties may enter into the preparation of an estimate, the moment you eliminate or neutralize one of these uncertainties by careful analysis and study, you are correspondingly closer to the actual result than if you guessed at them all.* As has been said before, no scheme will ever be devised or charts drawn so that a novice can make highway estimates. By the same token, nothing will ever be promulgated or known which will entirely eliminate the disappearance of paper profits. However, through use of brains, intelligent interpretation and application of previous costs, as well as a study and knowledge of conditions influencing costs, risks can be greatly minimized and a much more accurate and conservative result obtained than is possible by any other human method. Aptitude in estimating for all items of expense concerned in a job, will have to be built on experience and study in the actual conduct of construction.

Building Construction Courses in Engineering Schools

Details of the Thompson-Starrett Foundation at Yale and Union and of Proposed Similar Courses in England

SOME WEEKS ago it was announced that there were to be established at Yale University and Union College courses in building construction financed partly by a benefaction to be known as the Thompson-Starrett Foundation. The full details of these courses have not been worked out but there is given below a preliminary statement regarding each. The information about Yale is from Dean C. H. Warren, of the Sheffield Scientific School, and that about Union from Prof. F. P. McKibben. As a matter of collateral interest there is also presented an extract from a recent "London Letter" in the *Journal* of the American Institute of Architects, which notes the formation of somewhat similar courses in England.

Yale University Course—Through the generosity of Louis J. and Mary E. Horowitz, a very substantial sum of money has been placed at the disposal of the university to be used for defraying the expense connected with the establishment of a course which may serve to prepare young men for entering on a professional career in the field of building construction. To accompany his gift for the establishment of the course, Mr. Horowitz offers two very substantial prizes to assist worthy and capable young men in securing practical experience for a period of two years after graduation.

The receipt of this gift is of such recent date that the university authorities have not as yet had an opportunity to work out fully the details of the course. As outlined in a preliminary way, it is proposed, in accordance with Mr. Horowitz's wishes, to make the course in every way equivalent to the other engineering courses, with the expectation that graduates of the course will be prepared to enter upon work in the construction of modern buildings from a thoroughly scientific and engineering standpoint.

The course will be given under the auspices of the Sheffield Scientific School and will be associated with the Department of Civil Engineering. The study of architectural design will be in the hands of the Department of Architecture in the School of Fine Arts, and it is expected that students in architecture will be given the opportunity of electing special subjects in the course in building construction.

The work of the first two years will be substantially that of the other engineering courses. Students will enter the course from the freshman year and will in the sophomore year pursue the same fundamental subjects, such as mathematics, physics, and drawing, as do the other engineering students. In their junior year they will pursue courses in building design, stresses, structures, materials, economics, and accounting. This will be followed in the senior year by more advanced work in design and by such subjects as mechanical equipment of buildings, specifications and contracts, estimates, business law, and insurance. In this year they will also devote a substantial amount of time to a full year course in building construction in which they will be instructed in the application of the knowledge and principles which they have learned during the earlier

years of the course. During the vacations between undergraduate years practical work under supervision will be recommended or required.

The university is prepared to admit students to the first three years of the course. As it will be necessary to secure some men with a wide experience in actual building construction and otherwise competent to give the more specialized work of the senior year, it will probably not be possible to admit students to the senior year at the opening of the university in the fall.

It is the belief of the faculty at Yale that work in building construction will add a very important field to the university's educational program, and they are confident that it will develop into one of their strongest and most useful engineering courses. They also believe that the location of a course of this character in an engineering school closely affiliated with a strong architectural department argues well for the successful development of the course.

Union College Course—The president of the Thompson-Starrett Co., L. J. Horowitz, of New York, has also established a trust fund the income from which is to be used in part to provide training in building construction at Union College. A new four years' course or option in civil engineering has been authorized at Union with a view of affording as broad training in general engineering as possible in four years and at the same time offering therewith specialized work in the design, construction and estimating of buildings. A new professor will be appointed to teach the work in building construction and estimating.

From the graduating class two students are to be chosen each year to enter the Thompson-Starrett organization under the Foundation and remain two years, after which time they become a part of the company's regular force.

At Union the freshman and sophomore years will be exactly the same as now given to civil and electrical engineers—these two courses being identical for the first two years. The junior year will be similar to the regular course in civil engineering except that it will include work in building construction.

The work of the senior year will be as follows:

First Term	Second Term
Mechanical Equipment of Buildings 2	Reinforced Concrete 4
Structural Engineering and Design 6	Structures and Design . . . 4
Business Law 3	Contracts and Specifications 3
Building Construction 3	Building Construction . . . 3
Heat Engineering 3	Heat Engineering 3
Finance and Banking 3	Business Administration 3

The figures in the above table represent the number of exercises per week. Students who satisfactorily complete this course will receive the degree of B.S. in civil engineering.

Proposals in England—"Definite proposals appear to be on the tapis for the foundation in England of a School for Builders to provide for future builders, equal facilities to those enjoyed by intending architects.

"The school would be financed by the Federation of Builders, and would provide the equivalent of a university education with a sort of Master Builder's degree instead of the usual pass or honors degree in law, history, etc.

"The advantages of such a scheme are patent. The organization of a contractor's business is a very com-

plex one and there is no reason why the sons of master builders should not receive a full scientific school training both in theory and the elements of practice. This training would be completed by fuller practical work.

"From the architect's point of view the scheme offers the promise of a better standard of education in the building trade and consequently enhanced understanding between the trade and the profession. Limited collaboration with the big architectural schools would increase the advantages of education on both sides, and would incidentally make possible the conservation of many of the finer traditions of building which are being gradually lost with the spread of commercial building. A revival of the spirit of the craftsman in the operative would not be beyond the range of possibilities, and might counteract the tendency toward mechanical repetition in design. The site for the proposed school is still undetermined, but it is to be hoped that it will not be too far removed from the large architectural schools of the metropolis."

Hydro-Electric Plant with Head of Over One Mile

High-Head, Low-Flow Swiss Plant—Special Steel Penstock 15,200 Ft. Long—Unusual Design of Pelton Wheels

BY FRED A. NOETZLI

Chief Engineer, Bissell & Sinnicks, San Francisco, Calif.

A HYDRO-ELECTRIC power plant of 12,000 hp., operating under a head of practically one mile (1,650 meters), and having a single penstock of less than 2 ft. diameter, was recently constructed and successfully put in operation in Switzerland. The water utilized in this development is drawn from the little lake of Fully which is located in the westerly part of

the Swiss Alps at an altitude of about 7,000 ft. above sea level.

The lake is tapped by a tunnel and pipe line about 100 ft. below normal water level. The penstock extends from the intake at the lake bottom for a distance of approximately three miles down to the valley of the Rhone River. Fig. 1 shows the power house and the penstock location. Lake Fully is located behind the far mountain range through which the penstock pipe is carried in a tunnel.

Storage Increased by Pumping—The natural storage capacity of the lake, which is very small, was increased by the construction of an arched masonry dam 40 ft.

FIG. 1—GENERAL VIEW OF THE POWER HOUSE AND PENSTOCK

high. The useful storage above the intake tunnel is 2,600 acre-ft. Due to the high head this represents a stored energy of 10,000,000 kw.-hr. The power plant is used as a reserve for a low-head plant and is operated intermittently. This makes it possible to increase the quantity of water available from Lake Fully, which has a very small drainage area, by the addition of water pumped from a little lake located 450 ft. below Lake Fully. The penstock passes very near this lower lake, and a centrifugal pump, operated by a 640-hp. electrical motor and discharging directly into the penstock, pumps water from the lower lake through the penstock into the upper lake. The difference in elevation between the two lakes is approximately $\frac{1}{2}$ of the total head of the power plant. Inasmuch as the pumping efficiency averages about 50 per cent, the pumped water produces in the high-head plant six times the energy which is required to pump it to the upper lake.

The Penstock—The penstock has a total length of about 15,200 ft. and it is made up of a series of steel pipes of different diameters and thicknesses according to the head of water. The inside diameter of the upper 7,500 ft. is 24 in. (60 cm.) and of the lower 7,700 ft. is 20 in. (50 cm.). The thickness of the pipe is approximately $\frac{1}{2}$ in. at the intake, and increases in steps in proportion to the pressure, to 1 $\frac{1}{2}$ in. at the lowest point where the static head is 5,400 ft.

The pipes sustaining the greatest head were manufactured by a special process, and all pipes were tested

FIG. 2—METHOD OF MOUNTING RUNNER BUCKETS

One bucket is placed on top of the runner to show its construction.

in the shop for 50 per cent over the given pressure. The whole penstock was put about four feet underground, and no expansion joints were provided. Fig. 3 shows a profile of the penstock location. With the exception of three short tunnels, the trench follows closely the topography of the ground.

The whole penstock is built up of straight pipes 20 ft. to 40 ft. in length, according to the permissible weight of each section as limited by the transportation facilities. A special type of joint was used which permitted the making of small angles in the pipe line. Two wedge-shaped rings are inserted between the pipe ends, as illustrated in Fig. 4. By rotating these rings in a suitable manner relatively to each other and to the pipe-ends, any angle up to 10 deg. was obtained, either in a horizontal, vertical or inclined direction. This greatly facilitated the laying of the pipe. The pipes were fastened together by means of special flange rings and bolts, which for the lower portions of the penstock were made of nickel steel.

All joints were tested in the field for 25 per cent over-pressure. The excellence of the workmanship is well illustrated by the fact that the penstock has been in successful operation for several years although, in addition to the waterwheels, a battery of twelve hy-

FIG. 3—PROFILE OF THE PENSTOCK

The penstock passes by Lake Sorniot. Water from this lake is pumped to Lake Fully.

draulic presses which cause considerable fluctuation of the pressure in the penstock, is directly connected to the pipe line.

It need not be emphasized that particular attention was given to safety devices for protecting both the penstock and power house in case of breaks in the pipe line or a runaway condition of a waterwheel. As a matter of some interest in this connection may be mentioned novel automatic high-pressure needle valves which close at a pre-determined variable speed as soon as a serious disturbance of the water pressure in the penstock occurs. The time required for closing varies from 30 to 60 sec., so that no dangerous water-hammer can occur. When the power plant is operating at full load, the penstock delivers 28 sec.-ft. for the total 12,000 hp., and the velocity of the water in the penstock is about 13 ft. per sec. The loss of head for these conditions was calculated at 530 ft. or practically 10 per cent of the static head. Inasmuch as the power plant is a reserve installation, and will work at full capacity only during short periods of time, a 10 per cent loss of head was deemed permissible.

The Power Plant—The power plant is equipped with four units of 3,000 hp. each, arranged lengthwise with ample clearance to provide a maximum degree of safety in case that, for instance, a bucket should fly off. The waterwheels are of the Pelton type, and their construction and the design of nozzles and valves was unusually

FIG. 4—SPECIAL JOINTS IN THE PENSTOCK

The joints are provided with wedge-shape rings to allow for minor changes in alignment.

difficult owing to the large head under which they operate. Each 3,000-hp. unit is driven by a stream of water of 7 sec.-ft. issuing from a nozzle of 1 1/2 in. in diameter at the enormous velocity of about 540 ft. per second.

The buckets of the waterwheel are keyed into grooves on the circumference of the wheels and fastened thereto in the manner as illustrated by Fig. 2, thereby avoiding all screw connections. In order to assure a perfectly tight fit of the buckets in the grooves, the wheels were heated by an electric furnace before the buckets were inserted in the grooves. When the heat had expanded the wheel sufficiently the cold buckets were keyed into the

grooves. The contraction of the cooling steel of the wheel produced the desired result.

The speed of the waterwheels is held within close limits to avoid undesirable effects upon both the penstock and the machinery. If the load of a unit is thrown off instantaneously, the nozzle is deflected within 2 seconds, and the movement of the needle is timed so as gradually to close the nozzle in 40 seconds.

No unusual features are involved in the design of the generators. Each of the four units has a capacity of 2,800 kva. and generates three-phase current at 10,000 volts, and the power is transmitted at this voltage.

This project was designed and constructed under the direction of A. Boucher, hydraulic engineer, of Lausanne. All machinery was furnished by Swiss manufacturers. The power is used for electro-chemical purposes by the Société d'Electro-Chimie de Martigny, Switzerland. A detailed description of this development, which is the highest-head hydro-electric power plant that was ever built, is given in *Schweizerische Bauzeitung*, Nov. 25 to Dec. 30, 1922.

Quay Wall Reconstruction at Mare Island Navy Yard

Old Wall Embodied in New Structure Which Includes Concrete-Protected Ties Extending Inland 200 Ft.

By A. W. EARL

Supervising Engineer, Public Works Department, Mare Island Navy Yard

EARLY IN 1920 a serious outward movement began on about two-thirds of the entire length of a 3,600-ft. quay wall at the Mare Island Navy Yard in California. During the year this movement amounted to over 3 in. and culminated in the total failure of one stretch 120 ft. long. The wall was being subjected to

extensive damage in Mare Island and Carquinez Straits. Fortunately, with one short exception, quay walls at Mare Island were constructed with a timber bulkhead at the front of the wall which protected the wooden pile supports of the relieving platform. This made it possible to incorporate the old wall in a concrete structure of design suited to present needs. It also facilitated the new construction and made the removal of the old wall unnecessary.

The wall as reconstructed consists of a row of

DETAILS AND SPACING OF FORMS IN PILE CASTING YARD

PILE CASTING YARD AND MINING PLANT

Cantilever traveling crane supports at right. Finished piles in foreground spaced ready for next pour. Concrete mixing plant in left background.

pressure greatly in excess of that for which it was designated, and it was apparent that immediate steps toward reconstruction were necessary to prevent its complete collapse. An effective means of anchoring the reconstructed wall was worked out, using a system of long ties extending from a reinforced-concrete beam along the seawall to deadmen inshore.

The old wall was built in a number of short sections between 1898 and 1904. The type of construction varied somewhat but in general consisted of a concrete or ashlar faced rubble seawall supported on wooden piles. The walls were of the platform type with a timber sheet pile bulkhead in front of the rubble, masonry or concrete face wall. At the time the original wall was built naval vessels were much smaller than those of today and consequently a lesser depth was required alongside the wall than at present. As repeated increases in the draft of ships necessitated deeper dredging the wall was required to withstand a continually increasing pressure which finally resulted in partial failure. However, while the outward movement of the wall was the immediate reason for reconstruction, the work must have been undertaken in any event on account of the very serious damage caused by the teredo.

Previous to the year 1917 the waters of Mare Island Strait had been free from teredo and consequently all waterfront structures were constructed on timber foundations. Beginning in 1917 the teredo made their presence known and during the succeeding years caused

18x24-in. reinforced-concrete sheet piles driven with the inner faces about 6 ft. 6 in. outboard of the face of the old wall. These piles are driven until their tops are 1 ft. below the top of the wall and are tied back by steel rods to a horizontal reinforced-concrete girder which replaces the top portion of the old masonry face wall. This horizontal girder in turn is tied back at intervals varying from 30 to 60 ft. to concrete deadmen which are buried at distances varying from about 100 to 200 ft. back from the wall. The deadmen are buried with their tops 5 ft. below the surface and are 12 to 19 ft. long and 8 ft. deep.

The space between the back of the new concrete sheet piling and timber bulkhead under the old wall is filled with rock up to about 2 ft. above mean low water. The

PILEDRIVER AND PARTIALLY COMPLETED WALL

Note waling strip tied by rods into beam made of two channels which in turn is anchored in large concrete beam. Space between wall and sheet piling is concreted up to form service duct.

PLAN OF TYPICAL PORTION OF NEW CONCRETE SEAWALL

space between the concrete piling and the old face wall is utilized to form a corridor for the accommodation of service lines which, through outlets in the face of the wall, will supply ships berthed alongside with air, steam, electricity, fresh and salt water, and telephone service.

In addition to the 2,300 ft. of quay wall reconstructed on this plan, there remains about 1,300 ft. of wall to which, on account of different construction of the original wall and different conditions at the site, the design described will not apply without modification. Final designs for this remaining portion of the wall have not yet been developed.

Because of the urgent necessity of stopping further outward movement, the reconstruction of the old wall was started in November, 1920, with the limited funds available at that time. When the first 200-ft. section was completed it became necessary to stop work until Congress made a special appropriation for continuing it. This was done July 1, 1922. By July 1, 1923, about 900 ft. of wall had been finished and concrete piles had been cast for about 500 ft. more. The estimated cost for the 3,600 ft. of wall is \$1,260,000, or an average of \$350 per foot. The portion now under construction runs about \$325 per foot.

The work in its entirety will require approximately 2,400 reinforced-concrete sheet piles varying in length

from 50 to 60 ft. and consequently it was of the utmost importance to have an adequate casting plant. Fortunately, there was available a small ship-building slip, used during the war for the construction of destroyers, which is served by a traveling, ship-building-type cantilever crane of 15 tons capacity. This slip was adapted to service as a pile casting yard by flooring it with 2-in. plank to make a level platform 65 ft. wide by 400 ft. long. This area is sufficient for laying down 200 piles at one time. About midway of one side of this platform a concrete mixing plant was constructed, with the usual storage and bunker equipment. The bunkers are served by means of a locomotive crane and grab bucket operating on a track. The cantilever crane completely covers the whole area of the platform, and is used in placing forms and reinforcing frames, in transporting concrete from the mixing plant to the forms, and in transporting the finished piles to the barge which berths at the outboard end of the platform.

The forms used, shown in the accompanying illustration, have proved very satisfactory, being durable and easily placed. When first set up they are so spaced that the spacing of piles cast in the first pour is just right to permit the pouring of alternate piles between those already cast, thus conserving space and forms. The platform is constructed with two slots or openings

TYPICAL SECTION THROUGH WALL, TIE AND DEADMAN

about 6 in. wide running its full length transverse to the piles and at about the third point. Before the concrete is poured these slots are filled in with short pieces of 1-in. boards, which can later be removed from beneath to allow the use of jacks in separating the piles and to afford a convenient means of passing slings around the piles for lifting them.

It should be stated that the construction of the casting platform could have been improved by laying the plank flooring at right angles to the piles instead of parallel thereto. The unevenness between adjacent planks caused trouble in separating the piles, whereas if the planks had been laid the other way, in separating the piles, the movement would have been lengthwise of the planks instead of across them.

Considerable experimenting was done before a satisfactory coating was found to put on the sides of the concrete piles when casting the alternate piles between

FINISHED PILE BEING MOVED DOWN THE
CASTING YARD

Finished piles are delivered direct to barge moored at end of yard or stored in piles near that point awaiting transfer to the barge.

those from which the forms had been removed. It was finally determined that a mixture composed of two parts of axle grease and one part of rosin, melted together and applied hot, gave the most satisfactory results at the least cost.

In general the plant has been very satisfactory. When casting is proceeding opposite the mixing plant the rate of output is 20 piles in 8 hours. At the ends of the platform, because of the longer haul, this rate is decreased to 12 piles per day. The mixing plant has also proved very useful as a central plant from which to transport in trucks concrete for the horizontal girders, deadmen and other parts of the new wall, which are poured in place. The capacity of the plant for this work is somewhat over 200 cu.yd. a day. Exclusive of the fabrication of reinforcement the plant operates with a force of about 12 men.

When sufficiently cured the piles are transported on a barge from the outboard end of the casting platform to the site of the work. They are driven by means of a skid driver, fitted with a No. "0" Vulcan Steam hammer, operating on the face of the old wall. In general the driving has been very hard but little difficulty has been encountered due to breakage.

This work is under the cognizance of the Bureau of Yards and Docks, Rear Admiral L. E. Gregory, C. E. C. U. S. Navy, chief of the bureau. It is being done by yard labor under the immediate supervision of Captain L. M. Cox, the senior officer of the Corps of Civil Engineers of the Navy attached to the station at Mare Island.

Bates Road Tests Do Not Apply to City Streets

BY IVAN E. HOUK

City Engineer, Dayton, Ohio

WHILE the various articles describing the Bates road experiments have set forth the general conclusions which may be drawn from them, they have not made clear the fact that these conclusions are not necessarily 100 per cent applicable to city pavements. Many of the results can doubtless be applied to city streets. The conclusions regarding strength of brick, asphalt and asphaltic concrete surfaces as compared with the strength of the concrete base and those regarding different thicknesses of brick, different proportions of concrete, and so forth, as set forth in *Engineering News-Record* of Jan. 11, 1923, p. 57, probably hold for city streets as well as for country roads. However, it is doubtful if the conclusions regarding the relative thickness of the pavement in the center and at the edges can be applied to city pavements, except in special instances where some unusual circumstance throws the heavy traffic to the sides of the street.

In the first place city streets are wider than country roads. Then again practically all city streets have curbs at the edges of the roadway and sidewalks back of the curbs, built enough higher than the curbs to cause the water to drain into the gutters at the edges of the pavements, whereas, in the case of country road pavements, the sides of the road are generally lower than the edges of the pavement and slope downward toward drainage ditches at the sides. Therefore the conditions at the edges of a city street are much better as regards strength of foundation than are those at the edges of a country road. The straight curb, which is often used in the case of a concrete roadway, goes down into the ground several inches below the bottom of the pavement, extends several inches above the top and has earth back of it. Certainly this condition tends to hold the subgrade in place at the edges. The combined curb and gutter has the same effect, though probably not to so great a degree. Moreover city streets are generally well sewered. Consequently the subgrade at the edges is much less likely to become water-soaked.

On country roads the traffic generally follows the edges of the pavements, even though there are but few vehicles on the road. In the city the opposite situation prevails. There the traffic generally keeps near the center of the roadway, even though there may be nothing to prevent its following the edges. There are several reasons for this: (1) The parking of cars along the curbs requires the traffic to keep away from the edges; (2) Trees just back of the curbs often partially obstruct or cloud the view along the edges; (3) There seems to be an inherent tendency in the most of us to keep away from the gutter on the steeper portion of the crown whether we are driving slow or fast, whether cars are parked at the sides or not.

Improved Location and Equipment of Passing Tracks

Space Sidings by Time Rather than Distance and Operate Switches from Tower to Avoid Train Delays at Small Cost

THE LOCATION of passing sidings and the mechanical operation of their switches to avoid delays to trains are important factors to be considered by the engineer in connection with the effective or economic handling of traffic on busy single-track lines. This subject was included in a copyright paper on methods of increasing the traffic capacity of single-track railroads, read at the annual meeting of the American Association of Railroad Superintendents by Bertram H. Mann, signal engineer of the Missouri Pacific Ry. The purpose of his study was to show that operation of a freight-train district is a mathematical problem and that the proper balance of a budget for physical improvements to the road may have a close relation to this problem. His plan is based on careful analysis of train movements in relation to the positions of telegraph offices and passing sidings. The paper deals largely with operating conditions, but the portions which are of more direct interest to the engineer are summarized below.

In the first place, telegraph offices at sidings should be systematically spaced and these sidings should not be located arbitrarily at stations. Each run between telegraph offices should have at least one intermediate siding to provide for heavy traffic. In the second place, the spacing of sidings must be fairly uniform, with due allowance for grades and other conditions, in order to insure a steady movement of traffic. If the train periods between sidings vary considerably, the stream of traffic will be governed largely by the movements on the longest run. To handle traffic effectively on a single-track line whose business seems to call for double-tracking: (1) Trains must be forwarded from the starting point at such intervals as are determined by experience with average performance, and (2) the predetermined time periods between sidings must be maintained.

On a freight-train district the saving in operating expense which may be made by correct location of sidings and providing them with continuous-service telegraph offices is too great to permit of arranging them arbitrarily to coincide with traffic requirements by enabling the operators to sell tickets or handle freight at stations. On a single-track district of moderate traffic density the accounting item of "cost of freight-train train-miles" may amount to \$50,000 or even \$75,000 per month, divided equally between locomotive repairs, wages and fuel. A freight train run of 145 miles made in an average time of 12 hr. 5 min. costs \$201.19 for these three items, representing 28.7c. per minute or \$17.21 per hour.

In the art of handling a single-track railroad freight subdivision, any consideration of distance in locating the sidings is far from the point. The main question is the time spacing. Profile of grades is one factor in fixing the number of minutes for this time spacing between sidings, and another is the time required for service or work at the station. Traffic movement on single track must be in waves, and the best condition exists when the waves marked by adjacent sidings are equal and the continuity of flow is least broken at the sidings. The waves are made up of three parts: (1) running time between sidings, (2) time required to "head in" and "head out" at the sidings, and (3) time required at the siding. It has been held by many officers that a spacing of four to five miles for lap sidings on single track was sufficient for full

capacity owing to the delays involved by heading in and heading out of the siding. But such delays should not govern traffic movements or siding location.

Delays incident to taking sidings may be reduced materially by having the telegraph operators handle the switches mechanically. From the financial viewpoint a railroad can hardly afford the expense resulting from delays on districts operated by heavy engines and long trains, when these trains have to be stopped while their crews operate the switches. With a rule for one-direction traffic and all trains headed in at the lapped end of the sidings, it requires only small expense to install a simple mechanical interlocking plant with levers in the telegraph office. At the farther end of the siding, a remote-control low-voltage installation handled from the telegraph office, or a spring switch with automatic electric signals, will save a stop for the train when heading out to the main track. Such helps are in successful use.

Ordinary freight trains standing on sidetracks for more than 20 per cent of the time of the entire trip are subjects for investigation, but in many cases this period is from 30 to 40 per cent. For an average speed of 12½ m.p.h. from starting point to destination, an average speed of 20 m.p.h. between stops is required, and the aim should be an average speed of 20 m.p.h. between sidings, with idle time on sidings not exceeding 20 per cent of total time of run. The Adamson law has one good feature in that it has shown convincingly the gain of the moving train as opposed to the loss by unproductive time. Punitive pay for overtime of train crews stimulates a search for causes of delay when the desired speed cannot be maintained.

Four factors in the operating output of ton-miles are the ruling grade, the drawbar pull, the weight of train and the train speed. Further, every freight-train district has a characteristic movement or period. For development of traffic capacity this period must be determined, the train movement arranged in consonance with it and the spacing of sidings and telegraph stations made to synchronize with it.

Study of the problem of improving freight-train service develops certain laws of single-track operation and proves the money value of the mathematical operation of trains. Such a study prompts the use of special devices on the locomotive (booster, superheater, feed-water heater, thermic syphon and arch), of signal and interlocking plants, and, last but not least, of a uniform scheme for the operation and arrangement of sidings and siding facilities. The length of subdivision is fixed, so that the only variable factors are tonnage and time. For a meeting on single track under present train rules, the switch at which the inferior train takes siding becomes a "bumping post" or stopping point for the opposing train. With the recommended plan, it is feasible for both trains to drift the entire length of each siding at the meeting point. The next step is the extension of individual sidings as traffic demands, with a view to the ultimate double track.

In considering a budget for improvements there may be seven or eight freight-train districts or subdivisions which are not satisfactory as to performance. It is not unusual to select the worst subdivision and provide large outlays for double-tracking or grade reduction which builds up its capacity beyond its immediate traffic requirements, while nothing is done to the other subdivisions which equally require relief. The plan outlined above contemplates the study of each subdivision, with such rearrangement of siding, spacing and handling as will fairly meet the existing demands. The layout would permit growth as traffic increases until double track is reached eventually. Such a program will supply the needs of several subdivisions at a cost perhaps less than the single comprehensive overhauling of one selected subdivision. Waste of time by idle trains may be overcome in many cases by slight rearrangement of or addition to existing facilities.

Local Laboratory Control of Water Supplies in California

SUCCESSFUL chlorination depends on a certain amount of laboratory control under the immediate direction of the operator or water superintendent. Holding this viewpoint the California State Board of Health has recently undertaken to establish local laboratories wherever chlorination or any other treatment of the water supplies of the state is practiced. Once before the board tried to interest the officials of the various cities in laboratory control but the tests proposed were too elaborate and the work was gradually abandoned. Recently the procedure has been reduced to the simplest terms possible, viz., the bacterial count on agar before and after treatment.

C. G. Gillespie, director of the bureau of sanitary engineering, states that the making of the tests accomplishes three things: (1) It gives the people responsible for the supply a record of results achieved which, in case of litigation and damage suits, is most valuable. (2) It apprises the consumer and officials every

EQUIPMENT FOR BACTERIAL COUNTS			
Quantity	Description	Size	Price
1	Incubator, electric	12x12x12 in.	\$20.00

1 gal.	Distilled water		0.25
6	Disb towels		0.75

day as to just how successfully the supply is being safeguarded. (3) It stimulates the interest of the man in charge more than anything else he can do, because it gives him visible evidence and a yard stick by which to measure the results of his carefulness.

Operators of average intelligence have been taught without difficulty to make the tests and obtain reliable results. Mr. Gillespie states that in his opinion establishment of these local laboratories is one of the longest steps forward in putting chlorination on a more dependable basis.

W. F. Langelier, chemist, and bacteriologist for the board, has tabulated the following list of materials for equipping a "minimum" laboratory and given certain instructions, but he recommends that the operator visit Berkeley, or a laboratory already installed. Simple instructions are given for making media, sterilizing glassware, plating, incubation, counting and keeping records.

Low Sewage Sludge Freight Rates in England

Dried sewage sludge, bagged, will be carried at special rates by the railways of England hereafter, says the London *Surveyor*.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Dr. Waddell Asks Help for Japanese Engineers

Sir—Owing to the awful calamity that has just occurred in Japan, many of our brother engineers in that country must be in dire need, and will be for some time to come—as will be also the families of those engineers who have perished. It has struck me that it would be a kind and friendly act for the engineers of America to contribute individually but as engineers through the New York City Branch of the Yokohama Specie Bank, one-half of the money thus sent being used immediately for general relief of the suffering populace, and the other half later for engineers and their families. I have arranged with the manager of the bank to receive and distribute in that manner all moneys thus sent, working later through the Civil Engineering Society of Japan. Please make checks payable to Engineers' Relief Fund of Yokohama Specie Bank, the address being 120 Broadway, New York City.

For years it has been an earnest desire of mine to see the peoples of Japan and America brought permanently into harmony and close friendship, and if we Americans now help the Japanese generously in their hour of need, they will never forget it; because, from long personal experience, I know them to be a truly grateful and appreciative people.

I trust that each American engineer will contribute as liberally as he can, but even small amounts would help—on the principle that "mony a little macks a muckle."

New York City,
Sept. 4, 1923.

J. A. L. WADDELL,
Consulting Engineer.

[While we sympathize with Dr. Waddell's desire to render every aid to the Japanese sufferers we are inclined to doubt the desirability of separating the various aid funds by professions or other divisions. It seems to us that a much better way would be for everyone to contribute within his means to the American Red Cross.—EDITOR.]

Engineers in the Public Service

Sir—I take pleasure in reading your editorial comment in the current issue on the explanation offered by the Secretary of the Interior relative to the reorganization of the U. S. Reclamation service.

Leaving aside personalities, it is well known how often engineers are supplanted in this country by so-called business men as soon as the major construction problems have been solved. It cannot be contended that all engineers are necessarily good business men but there are abundant examples where engineers have succeeded in the business sense because of special fitness for administration and operation of engineering works.

In the public service every citizen has a right and duty to demand that the best possible service shall be given. It is certainly reasonable that heads of departments having vast engineering enterprises in charge should themselves be engineers of the highest qualifications. It is deplorable that politicians or so-called business men should get control and subordinate or dominate at will those who do possess the ability to manage these nation's enterprises. Each time it occurs, vigorous opposition should be given. Let engineering work be done by engineers and let them have the honor—yes, and the pay, too.

Newport News, Va.

GEORGE C. LOVE,
Consulting Engineer.

August 25, 1923.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

The Contract Has Been Let for the First 25 miles of the new railway being built by the Ontario Government from Swastika to Larder Lake in the gold mining region of Northern Ontario. It is expected that it will be completed as far as Kirkland Lake this fall.

The British Columbia Government is continuing work on its reclamation project near Sumas. Thirty thousand acres of land that lie along the Fraser River are being protected from the river by concrete dikes and water from this low land is to be pumped up into the river by four electric pumps of a capacity of 1,250 hp. each.

Arrangements Have Been Effected by the Montreal and Quebec interests for the organization of the Laurentide Hydro-Electric Power Co. Ltd. Power rights have been acquired on the North River near St. Adele and the company will be in position to serve the industrial centers of St. Agathe, Piedmont, St. Margaret, Strawbridge and St. Adele.

Contracts for Two Extensions to northern Alberta railways, viz.: thirteen miles west of Berwyn, north of Peach River, Alberta, and fifteen miles to Lake Saskatchewan, west of Grand Prairie, on the Canada Central Ry., have been let by the government to James Mohler, Sr., of Oshon, and construction will be commenced shortly, though it is not thought probable that the work will be completed in time to be of service in handling this year's crop.

Plans Are Being Prepared for a dam 400 ft. long across the North branch of the Ottawa River near Bryson, Quebec, and for a transmission line about 50 miles long to Ottawa, Ontario. This plant is being built by the Ottawa River Power Co., a subsidiary of the Ottawa and Hull Power Co., Ltd., and will add 9,000 hp. to the 31,000-hp. capacity of the two plants of this company on the Ottawa River near Ottawa. In addition, the company controls at Bryson, Quebec, another power site capable of developing 60,000 hp.

D. C. Coleman, Vice-President of the Canadian Pacific Ry., Western lines, states that the branch line program carried out this year will bring into operation on the prairies a larger mileage than any year since 1914. Of the 431 miles of line under construction 281 miles will be ready for grain handling in the fall if sufficient labor is available. Branch lines complete and ready for grain handling are the Consul Easterly 60 miles; Rustown 45 miles; and Naicam to Melfort 32 miles. Most of the lines constructed or under construction tap territories hitherto without railway service or too far from lines to make extensive farming profitable on account of the long haul.

Miners Strike as Pinchot's Plan Fails

Strike of about 155,000 anthracite miners in the Pennsylvania fields began last Saturday, when representatives of the United Mine Workers of America and the operators were unable to agree on the terms of the compromise plan of Governor Pinchot.

Governor Pinchot's plan included: recognition of the basic eight-hour law for all employees; a uniform increase in pay of 10 per cent; full recognition of the union by the operators, without the check-off, but with the right to have a union representative present when the men were paid; and complete recognition of the principle of collective bargaining.

Though the miners have gone out, apparently doors are not closed to the Pinchot plan, as conferences between contesting parties are being carried on, without, however, any suggestions so far from the U. S. Coal Commission, which body has kept entirely out of the negotiations since the unsuccessful attempt it made two weeks ago to avert the strike by calling the New York City conference.

Economy to Be the Policy of the New York Public Works Dept.

Special Correspondence

The policy of the re-organized Public Works Department of the State of New York is to be one of economy according to the new superintendent, Col. Greene. He is reported to have said that "the idea of this consolidation is not more jobs, but fewer jobs just as soon as I can find a way to do it."

Among the early economies hoped to be effected is the housing under one roof of the canal and highway divisions and the consolidation of the two bridge and grade crossing elimination divisions now in the department of highways. Under the new law the superintendent has the right to abolish any position or to consolidate it with another and all of the appropriations made for the various departments are lumped. Consequently the personal patronage at the disposal of Col. Greene is enormous, totaling in excess of \$4,370,000. In the highway division, outside of the \$240,000 for the Albany office, there was appropriated this year for engineering supervision, inspectors, laborers, mechanics, chauffeurs and trucks on the nine highway divisions of the state \$2,290,000; the division of public works has at its disposal \$1,540,000 for personal service while the division of public buildings has \$300,000.

Amongst political leaders the appointment of Col. Greene is not entirely a popular one because of his known desire for economy and its possible effect on the barge canal situation.

The waterways advocates have been most active in circulating stories that the opposition, convinced that the canal is a failure, has advised the Governor to abandon the canal for navigation purposes and use its flow for the production of hydro-electric energy.

Colonel Greene Heads New York Public Works Department

Frederick Stuart Greene, commissioner of highways, has been named superintendent of Public Works of the State of New York under the reorganization bill which went into effect July 1, 1923. The appointment, which expires with that of the Governor, must be confirmed by the Senate when it convenes in January next. The reorganized department of public works, as outlined in *Engineering News-Record* May 17, p. 895, and June 7, p. 1015, includes the commission of boundary waters, the department of highways, the interstate bridge commission, and the department of public buildings.

Edward S. Walsh, superintendent of public works before the reorganization became law, has been appointed commissioner of canals and waterways; Lowell Grossman has been appointed to head the highway division, and John J. McNulty has been reappointed as head of the department of public buildings.

Colonel Greene has been engaged in engineering work since 1893. He is a graduate civil engineer of Virginia Military Institute and a member of the Am. Soc. C. E. Previous to 1917 he was engaged in highway, tunnel, subway and foundation work, chiefly in New York State. He served through the war as a battalion commander with a combat engineer regiment of the 77th Division. In April 1919 he was appointed commissioner of highways by Gov. Smith, which position he held until asked to resign by Gov. Miller in 1921, but was reappointed this year by Gov. Smith. In the interim he was in highway work, both in Panama and in Pennsylvania.

Edward S. Walsh has been prominent in canal transportation for years. He was deputy superintendent of public works in 1919 and later superintendent, and was reappointed by Gov. Smith in 1923.

Lowell Grossman has been in the state highway and engineering department since 1906, having worked his way up from rodman to assistant to the first deputy. During the war he served as a captain with the 23rd Engineers.

Reappointment Confirms Positions of California Officials

In accordance with an opinion recently rendered by the attorney-general of California, the act passed by the last legislature divorcing the state department of public works from the state highway commission, made it necessary for the Governor to reappoint the heads of both these departments. This was done on Aug. 27, the appointment confirming the positions held by W. F. McClure, state engineer and director of the reorganized department of public works, Robert M. Morton, highway engineer and Harvey M. Toy, Louis Everding and Nelson T. Edwards as members of the state highway commission.

\$1,000,000 So Far Raised for Sesqui-Centennial

Exposition Building Program Includes
Expenditure of \$15,000,000—
Engineers Are Active

Definite progress has been made in the development of the organization and of detailed plans for the sesqui-centennial exposition in Philadelphia in 1926 by the Sesqui-Centennial Exhibition Association, the organization of which was noted in *Engineering News-Record* March 30, 1922, p. 543. To date a million dollars has been subscribed to the Association by individuals and corporations, and plans are complete for a campaign to raise five million dollars by sale of bonds to the public. Five million dollars has been pledged by the city of Philadelphia. Five million more will be secured from other sources, making a total of fifteen million dollars, which is the estimated cost of building the exposition.

The site for the exposition begins on the Parkway at Logan Square, and extends through Fairmont Park to include the buildings and grounds on the west side of the river used for the Centennial Exposition. Schuylkill River flows down the middle, and at either side are rolling banks topped by broad plateaus. The trees and shrubbery are of mature age, and so set as to be usable for decorative purposes. The grounds as now outlined include 515 acres, and the buildings already projected contain 60 acres, and are arranged to permit of such further extension as may be required.

CONSTRUCTION PROGRAM

It is proposed that construction on a large scale shall begin in the Spring of 1924, giving a year to prepare the grounds and get the buildings ready for the installation of exhibits, and another year for the completion of the project. The gates will open on April 30, and will close on Nov. 13, 1926.

Engineering problems involved in the development of the site are simplified by the inclusion within the area of a number of permanent buildings, and by the fact that the area is now developed park land with roads and paths and supplied with sewage and water facilities. Permanent buildings on the site include the Philadelphia Art Museum and the Philadelphia Free Library, both of which are now under construction, and the Pennsylvania Museum and Horticultural Hall, which were built for the Centennial Exposition. The United States Government and the Commonwealth of Pennsylvania will be asked to construct permanent buildings to house their exhibits. Victory Hall, a convention hall planned as a memorial to the Philadelphians killed in the World War, is within the site and will be completed when the Exposition opens. The women of Pennsylvania are planning to construct a large permanent hospital. Some of the other buildings will be of temporary nature, to be removed when the Exposition closes, but many of the buildings will be of semi-permanent nature, to last for fifty years or more.

In the organization to carry on the work of the Sesqui-Centennial, engineers have from the start played leading roles. The executive director of the association is Col. John Price Jackson. Directors and department chiefs are

Brazilian Railway to Electrify 35 Additional Miles

Contract for upward of \$1,000,000 worth of electrical equipment has been awarded to the International General Electric Co. by the Paulista Ry. of Brazil for the electrification of 35 additional miles of its railway. This contract is in addition to the one awarded to the General Electric Co. in 1920 for 28 miles of double track electrification, and brings the total electrified mileage up to 63 miles, starting at Jundiáhy and extending north to Tatu. This is approximately half the total mileage which the Paulista Ry. intends to electrify. The new order includes five 62-ton, 3,000-volt, d.c. switching locomotives, a complete substation of 4,500-kw., and auxiliary equipment for the overhead line and the transmission line.

New Secretary, A. P. H. A., Is Sanitary Engineer

Homer N. Calver, since July 1 acting secretary of the American Public Health Association, was graduated in sanitary engineering from the Massachusetts Institute of Technology and afterwards became assistant health officer of Winston-Salem, N. C. During the war he served in France as an ambulance driver and then in the sanitary corps, attaining a captaincy and the command of a mobile field laboratory. After the war he was for a time acting director of the health service, American Red Cross, and recently he has been engaged in a survey of child health agencies in New York City, under the Public Health Committee of the New York Academy of Medicine.

Large Power Development Planned for Alaska

In connection with the announcement that the government has made a conditional sale of 334,000,000 ft. of timber in the Cascade Creek unit on Thomas Bay in the Tongass National Forest of Alaska to the firm of Hutton, McNear & Dougherty of San Francisco, it was announced that the purchaser has agreed as part of the consideration to build a pulp manufacturing plant of not less than 100 tons daily and of an ultimate capacity of 200 tons at the Cascade Creek water power site on Thomas Bay 20 miles from Petersburg, Alaska. The estimated capacity of this site is 23,700 hp.

Licenses to develop the water power in the National Forest of Alaska are obtained from the Federal Power Commission under an arrangement which allocates the power sites to the manufacturers of the timber most logically available to them. The Forest Service and the Federal Power Commission are collaborating in a survey of the more important water powers in southeastern Alaska which will ultimately be developed in establishing the paper industry.

now being selected tentatively, and will be appointed after the public sale of bonds is complete. The grounds and buildings committee, one of the most important committees, has a total membership of 54, of whom 19 are engineers.

Engineering Editors Broadcast from New York

All during this summer various editors of the McGraw-Hill Co., Inc., have been broadcasting short talks on engineering information from station WJC in New York City. This will continue through the fall and the program as at present arranged is for Wednesday, from 8:15 to 8:30 p.m. The schedule so far determined is as follows:

September 5, Earl E. Whitehorse, commercial editor, *Electrical World*: "Who Has More Slaves than Pharaoh—A Talk on Electricity."

September 12, Kenneth H. Condit, editor, *American Machinist*: "Automatic Machines and Their Effect on Men."

September 19, H. C. Parmelee, editor, *Chemical & Metallurgical Engineering*: "The Work of the Chemical Engineer."

September 26, E. J. Mehren, editor, *Engineering News-Record*: "What Engineering Is and What It's Not."

Skill and Responsibility Required in Concrete Sea Wall Bidders

Skill and responsibility of bidder was announced as being of first consideration in the awarding of the contract for the construction of a concrete sea wall at Vicksburg, Miss. This attitude was taken in view of the fact that the work was of a special nature and needed to be handled with skill and dispatch in order that it will be finished by the next season of high water, and a statement to this effect was included in the "information for bidders." Each bidder was required to fill out a questionnaire giving the following information and attach it to his bid:

Length of time in the contracting business and in responsible charge of work, educational qualifications and training, outline of work similar to that under consideration, training and experience of the proposed superintendent in charge of the work, whether any part of the work is to be sublet, etc.

To discover the integrity of the bidders the following were among the points to be determined: Names and addresses of responsible references, information as to whether any work had been taken away from bidders because of dissatisfaction of owner or engineer, controversies with subcontractors, information as to whether any bidders had been involved in lawsuits.

As a result of the questionnaire only the most reputable contractors submitted bids, according to the Miller-Butterworth Co., of Little Rock, Ark., who had charge of engineering. These bids follow:

Mills Engineering Co., Tupelo, Miss., \$322,417.50; Doullut-Williams, New Orleans, La., \$307,133.35; Delta Cement & Tile Co., Greenville, Miss., \$349,822; Jefferson Construction Co., New Orleans, La., \$259,402.40; List & Weatherly Const. Co., Kansas City, Mo., \$274,850.07; Case & Cothran, Atlanta, Ga., \$326,102.75.

The questionnaire stated that the information required would be treated in strict confidence, that it would be returned immediately after it had served its purpose and no copy kept, and that questionnaires submitted by contractors whose work along similar lines was well known to the chief engineer would be returned unopened.

Random Lines

Why Contractors Are So Wild

In the Hermitage, Mo., *Index*, the following proposal advertisement recently appeared. Unfortunately there is not time for contractors all over the country to get in bids:

Notice is hereby given that separate bids will be received by the undersigned acting County Highway Engineer until 12 o'clock noon, MONDAY, SEPTEMBER 3rd 1923, for the following project at the Habert Bridge across Pommie de Terre on Pittsburg-Elkton Public road as follows:

The erection of five concrete piers upon which to place approaches of said bridge described as follows: Length at top of pier 14 feet and 6 inches; Top thickness 18 inches; Bottom of pier 3 feet under surface same size at surface which shall be two inches longer than at top for every foot in height. Thickness at base and at top of ground 36 inches; to be so placed that center of pier nearest bridge shall be 16 feet from center of heavy steel beam connecting and resting upon iron tube piers at end of bridge. The next pier to be 16 feet from first in same manner, and so on. The height of the piers shall be to a line drawn from top of said heavy iron beam at top and end of bridge to top of concrete pier at end of dirt fill at each end of bridge. Two of said piers to be placed on one side of river and three on other side to fill space. These piers to be paid for by the cubic yard, the person building same shall furnish his own material including concrete and forms. Concrete to be made of one part cement to six parts of clean gravel which shall be approximately one fourth sand. Also this work will include the furnishing and placing of one bolt 8 inches long and size to fit each hole in I beams and channels for support of floor. Said to be so placed that the holes in beams will fit same. Concrete to be well reinforced with barbed wire which the builder will also furnish.

* * *

Even in France

An American engineer resident in France sends an advertisement of the Temple Tours which reads "Our travel engineers are at your service . . . Telephone or call for particulars of delightful tours."

* * *

Last week it was reported in the newspapers that a road laborer in Maryland had dug up a box with \$10,000 (some said \$100,000) in gold coin in it. Since then the laborer has claimed that it was all a hoax. We thought there was something fishy about the first report. It was the first time we ever heard of anyone admitting there was money in road building.

* * *

Life is getting so complex. Now there's a "new industrial science"—fence building. One of the advertised functions of a fence company "includes the services of highly specialized fence experts, using blue prints, contour maps and mathematical formulae unknown to laymen."

125,000-Hp. Hydro-Electric Plant Proposed for West Virginia

Washington Correspondence

In reply to the protest of the Norfolk & Western R.R., the Chesapeake & Ohio R.R., and the Appalachian Power Co., against approving the application of the West Virginia Power Co., for a license to develop power on the New River below Anderson Falls, the Federal Power Commission states that its engineering staff proposes recommending the approval of the application. The proposed development would drown out the proposed plant of the Appalachian Power Co. at Anderson Falls and its steam plant at Glen Lyn.

The commission's engineers maintain that the West Virginia Power Co.'s project is more comprehensive than the one at Anderson Falls and is preferable to it, and that the question of damage from backwater is a routine one. The proposed development of the West Virginia Power Co. will produce 125,000 hp.

Hearing on Colorado River Project Set for Sept. 24

Washington Correspondence

A hearing which may be expected to bring out fully the conflicting views regarding power and irrigation rights along the Colorado River and which probably will have an important bearing on the pending compact among the states interested will be held Sept. 24 before the Federal Power Commission in Washington.

J. B. Girand, who holds a preliminary permit for development of a hydroelectric project on Diamond Creek, Arizona, recently wrote the Commission asking that action be taken on his application for a license which has been pending since March, 1922, or that he be permitted to present arguments in behalf of the application. A few days later, the governor of Arizona wrote the Commission requesting a conference between that body and a committee of Arizona citizens on the Girand application and the Colorado river problem in general.

In view of these requests, the Commission has notified Mr. Girand to appear before the Commission Sept. 24, and the governor of Arizona has been notified that a committee of citizens or officials from his state will be received on the same date. In order that all interests may be represented, the Commission has invited the governors of Colorado, Wyoming, Utah, New Mexico, Nevada and California to send representatives to this hearing.

The proposed convention for use of the Colorado River waters has been ratified by all the states excepting Arizona and has been advocated earnestly by Secretary of Commerce Hoover as a means of obtaining maximum development in that valley.

An interesting angle of the situation is that the Arizona State permit held by Mr. Girand, which was granted as the last act of Water Commissioner Norviel, will expire Dec. 31 by default if work is not started under its terms, and it is generally believed that, owing to a change in state administration, he would experience considerable difficulty in securing a renewal. But he cannot proceed under the state permit without a license from the Federal Power Commission, which has withheld action on his application for a year and a half.

Commission Changes Bidding Basis for Delaware Bridge Cables

Readvertisement of the contract for the cables of the Delaware River Bridge upon the basis of reduced quantities of work, was directed by the Delaware River Bridge Joint Commission at a special meeting on Wednesday, August 29. Bids had been received for the cables on August 15, but were rejected because the low bid was in excess of the funds available for the purpose. The changes in the amount of work are intended to bring it within the available limits.

The changes made in the work involve the elimination of all castings for attachment of suspenders to the cables, and elimination of the hand ropes, together with a reduction in the quantities of other items except the cable wire itself. Suspender rope is to be furnished in sufficient quantity for construction of the erection foot bridges, but the rope is not to be cut to length.

Suspenders, sockets, and suspender castings will be furnished and erected later under another contract. The estimated quantities of work on the new basis are as follows:

Item 1 Wire Cables	13,500,000 lb.
Item 2 Suspender Rope	50,000 ft.
Item 3 Castings	180,000 lb.
Item 4 High Tensile Bolts	6,000 lb.
Item 5 Structural Steel Shims	30,000 lb.
Item 6 Cast Iron Separators	30,000 lb.

Bids for the work are to be opened on September 19.

Geological Survey Begins Texas Topographic Study

Washington Correspondence

Engineers of the United States Geological Survey began work September 1 on a topographic survey of sections of Texas in co-operation with the State Water Board. Before the end of the month, Glenn S. Smith, chief engineer of the topographic division, expects to have 50 engineers working on the survey.

The work is in connection with the plans of Texas to control the flood waters of the streams of that state which have done millions of dollars of damage in the last few years. The plan contemplates creation of reservoirs to store surplus water and linked with this are plans for irrigation, reclamation and power projects.

The work will require two years. For the first year, the Geological Survey has made plans to spend nearly \$100,000 and hopes to be able to make a similar allotment in the second year in order that the work may not be delayed. This amount will be matched by the state, which has appropriated to various funds \$600,000 for topographic work. Charles E. Cooke, who is engineer in charge for the Geological Survey in the Texas work, has been in the state making arrangements several weeks.

More states have asked to participate in the federal co-operative topographic surveys this year than ever before. Some work will be done in 27 different states. The federal appropriation available for field topographic work under the co-operative plan this year is approximately \$400,000.

Civil Service Examinations UNITED STATES

For the U. S. Civil Service examinations listed below, apply to the United States Civil Service Commission, Washington, D. C., or to any local office of the Civil Service Commission.

Superintendent of Construction—Vacancies in the Central Office of the Veterans' Bureau, Washington, D. C., for field work on building projects of the Bureau, salary \$3,000 to \$3,600 per year, rating to be by sworn statement of applicant and corroborative evidence. Application must be filed by or before September 25.

Computer—Vacancies in the Coast and Geodetic Survey for duty in Washington, D. C., at an entrance salary of \$1,400 a year plus increase of \$20 a month; for duty in the Manila, P. I., office at entrance salary of \$2,000 a year plus \$20 a month increase; and for duty in computing the triangulation of the Hawaiian Islands, at entrance salary of \$1,860 a year. Examination will be held throughout the country on October 4 and 5.

Information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or from the secretary of any local examining board.

Engineering Societies

Calendar

Annual Meetings

NEW ENGLAND WATER WORKS ASSOCIATION, Boston, Mass.; Annual Convention, Burlington, Vt., Sept. 18-21, 1923.

INTERNATIONAL ASSOCIATION OF STREET SANITATION OFFICIALS, Chicago, Ill.; Annual Conference, Chicago, Sept. 27-28, 1923.

AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 5-11.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 17-20.

AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga.; Nov. 12 to 16.

CITY MANAGERS ASSOCIATION, Lawrence, Kansas; Annual Meeting, Washington, D. C., Nov. 13-15.

Society of Terminal Engineers, New York City, will have as its speaker at a meeting Sept. 11 F. W. Hersey, director of commerce of Wilmington, Del. The meeting will be held in the Engineering Societies Building at 8 p.m.

The Western Society of Engineers' opening fall meeting will be held Sept. 10, when E. Marshall, electrical engineer, Great Northern R.R., will speak on "Railroad Electrification." Other subjects for September are as follows: M. M. Leighton, chief, Illinois State Geological Survey, Sept. 17 on "Influence of Geology on Engineering" and W. A. Gildack, superintendent, W. K. Lithall Co., on the "Gravel-Washing Plant at Forreston, Ill.," one of the largest in the world.

Personal Notes

H. A. THACKREY has opened an office for general engineering practice in Camden, Ark. Mr. Thackrey is a civil engineer graduate of Kansas State Agricultural College, year 1914.

H. L. OGLE has been made junior partner of the M. Miller Co., contractors and engineers, New York City. Mr. Ogle was formerly district sales manager for the Youngstown Pressed Steel Co., Warren, Ohio.

MAURICE AYER, Fort Myers, Florida, has been made assistant engineer with A. L. White, civil engineer, Fort Myers, in general engineering practice and in drainage work.

JAMES R. NEVIN, formerly foreman with Harness Bros., general contractors, Ottumwa, Iowa, has been appointed a junior highway engineer in the service of the Illinois State Highway Commission.

LOUIS PARENT, city architect of Montreal, has resigned from the service of the department of public works of the city. Mr. Parent is the architect who designed the new city hall of Montreal, now under construction.

H. F. FLAGG, chief engineer of the State Board of Public Works at Olympia, Wash., has been selected by appraisal engineers of the city of Yakima and the Pacific Power & Light Co. to arbitrate reports of other engineers in fixing the valuation of the Pacific Power & Light Co.'s water system which the city is contemplating purchasing. The three engineers on the board have already begun their sessions in Olympia.

HERBERT HOOVER was elected to honorary membership in the Czechoslovak Engineers and Architects Association, at the annual conference of the association held recently at Kosice, Czechoslovakia, in recognition of "merit in engineering science and practice and good rendered to our people." Mr. Hoover was chairman of the Committee on Elimination of Waste in Industry, of the Federated American Engineering Societies, whose report has been translated by the Government of Czechoslovakia and distributed to the industries and educational institutions of that country.

CARL SITTINGER, Winchester, Mass., is now senior engineer with Stone & Webster, Boston, Mass., in the division of engineering and construction. For the past twelve years Mr. Sittinger was associated with John A. Stevens, consulting engineer, Lowell, Mass., as district manager of the Southern New England office and later as a director in the firm. During the War he was in charge of plant engineering for the Bethlehem Loading Co., a subsidiary of the Bethlehem Steel Corp., which was commissioned by the Government to design, construct and operate a large plant for the manufacture of high-explosive shells.

ROY C. MORTON, a civil engineering graduate of the University of North Carolina, has been appointed assistant

sanitary engineer in the Tennessee State Department of Health.

JAMES S. WATSON has been made resident engineer, at Philadelphia, for the Bethlehem Steel Co., Bethlehem, Pa.

A. D. DUCK, county engineer of Hunt County, Texas, at Greenville, has resigned to devote his time to the office of city engineer of Greenville which he has held for some time. G. R. Burtner, assistant engineer, has been appointed county engineer.

VAN CAMP, recently assistant engineer of San Augustine County, Texas, and later of Somervell County, has been appointed resident engineer in charge of construction for Tarrant County under D. A. Davis, county engineer at Ft. Worth.

JOPLING-MARSHALL CONST. Co. has opened offices as general contractors at 222 Slaughter Bldg., Dallas. The firm is composed of J. C. JOPLING of Wichita Falls and ALLAN F. MARSHALL of Dallas.

J. C. DUNBAR, president of the Big 4 Engineering Co. and the Anaconda Gravel Co., Ft. Worth, Tex., was recently appointed colonel of the 11th Engineers, 36th Division. Col. Dunbar served as major with this regiment in France.

JOHN W. REID has been appointed Commissioner of Public Works for the city of Detroit to fill the vacancy caused by the resignation of JOSEPH A. MARTIN. Mr. Reid has been connected with the Department of Public Works since 1900 when he entered as a draftsman in the city engineer's office. He was engineer in charge of the grade-separation division from the time it was organized until March 16, 1922, when he was appointed city engineer. The new commissioner has been in close contact with the design and construction work of the department and the present grade-separation activities in Detroit are attributed largely to his efforts. Mr. Reid will appoint a city engineer in accordance with his power as Commissioner of Public Works.

C. E. SLONOKER has resigned as resident engineer with the Tennessee Highway Department and will go into private practice in Johnson City, Tenn.

Obituary

WILLIAM C. CLEMENT, formerly city engineer of Vancouver, B. C., and previous to that assistant city engineer for sixteen years at Toronto, Ontario, died recently at Somenos, B. C., aged 60 years. Mr. Clement had been living on a ranch at Somenos.

FRANK G. DRUM, for many years a leader in business and financial circles in California died in San Francisco on Aug. 28. Three years ago he resigned the presidency of the Pacific Gas and Electric Co., which he had held for thirteen years. At the time of his death he was identified with many financial and public utility organizations of central California and among other offices, held the presidency of the Yosemite Valley R.R. Co. and vice-presidency of the Pacific Portland Cement Co., Consolidated.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Building Concrete Roads in Half Widths Affects Use of Finishing Machine

Manufacturers Point Out Need for Revision of Methods and Equipment to Meet New Conditions Imposed by Road Builders

TO care for traffic during the construction of a concrete road, particularly where detours can not readily be utilized, many of the state highway departments have resorted to the practice of building pavements in half-widths, thus providing a route for vehicles on one side while the other side is occupied by the contractor's operations. As a general rule this form of construction is more costly than if the slab were poured its full width in one operation. The argument for it is that the added expense is justified by the service rendered to traffic.

Aside from the economies of this practice, viewed solely from the angle

wheels for the second strip of pavement. The outside wheels, which run on the road forms, are double flanged, while the inside wheels, which travel on the concrete, are flat tread. The outside wheels serve to hold the machine in line with the double flange. When this method was first proposed it was thought it might be necessary to provide a metal plate on the concrete on which the flat-tread wheels could run. Actual operation has shown this to be unnecessary.

This method of building half-width roads was first used on an experimental road in France. That this method is practical was clearly demonstrated by this job, where the finishing

present machine is accomplishing. If a demand comes from the contractors for a machine to handle this narrow work, we will build a machine to take care of the demand. It is our understanding, however, that in all cases where these narrow width roads are built, the highway departments offer the contractor the privilege of doing the work by hand instead of by machine and unless we can produce a machine which will be comparatively low-priced the contractor will not be interested.

It is evident that a road built in two sections is going to cost the state and the taxpayers considerably more than the full-width road. From the engineering standpoint there may be some real reason for carrying the work on in this way, but so far I am not convinced that the two halves are as strong or as good as a full-width road, with concrete all across, or with a dividing plate in the middle, as built in some of the states.

By W. J. SAVAGE

Heltzel Steel Form & Iron Co., Warren, Ohio

The use of a full-width finishing machine will not be advantageous on half-width construction if the highway engineers insist on leaving half the road open to permit the passing of traffic alongside new construction where

HALF-WIDTH FINISHING ON IDEAL SECTION, LINCOLN HIGHWAY, AND NEW 9-FT. FINISHING MACHINE (LAKEWOOD)

of traffic, another important problem is involved in the use of mechanical equipment for finishing the half-width concrete slabs. Most of the concrete-road finishing machines were originally designed for full-width slabs of 18 ft., more or less. Present practice is calling for the finishing of 9 or 10 ft. slabs, which imposes on the manufacturer of equipment for this purpose the problem of adapting the full-width machine to the half-width slab or designing a new machine for the narrower work. To get the point of view of the manufacturer on this subject *Engineering News-Record* queried several of the makers of finishing machines; their replies follow:

By T. W. DIECKMANN

Paving Department, Lakewood
Engineering Co., Cleveland

When the method of building concrete roads in half-widths was first proposed we immediately gave attention to the use of the finishing machine on this type of construction. The first half-width, of course, could be machine-finished in the same way as any narrow concrete road. The problem was to finish the second strip.

We developed the method of equipping the finisher with a special set of

machine was handled by men who had not had a great deal of experience with such equipment. This method was also used by J. C. O'Connor & Sons for the construction of the Ideal Section of the Lincoln Highway, a 40-ft. pavement. The contractor used a 20-ft. finishing machine in the above manner with satisfactory results.

We have sold a number of 9- and 10-ft. finishers this year for 18- and 20-ft. roads that are being constructed in half-widths. A photograph of the 9-ft. finisher is reproduced herewith. There is also illustrated the use of the 20-ft. finishing machine on the 40-ft. Ideal Section of the Lincoln Highway.

By PAYNE G. WEST

Dunn Road Machinery Co., Conneaut, Ohio

We have discussed ways and means of trying to adapt our present machine to the narrow widths. We can cut down to the 9-ft. width, but not to the 8-ft., as our machine cannot be accommodated to this width. Later this year or next year we will probably go into the matter further and design a new machine, especially prepared for narrow widths. This would of necessity be a lighter and less expensive machine and as a result might fail to accomplish the big results which the

detours are not available. Further, we do not believe the method is practical even if the road were closed to traffic, as it would necessitate the setting of forms three times, putting the contractor to considerable expense. Even if this expense were disregarded, when the contractor started pouring the second half of the road, the tamper would be constantly hitting the finished road, causing some damage. Even this method would be impractical, as the finished half of the road would necessarily be covered either with straw or dirt for curing purposes, which would interfere with the proper functioning of the tamper strikeoff and belt.

We will shortly have a 9-ft. machine in operation on a half-width road. The use of a full-width machine on half-width construction is an expense to the contractor, unless of course provisions are made by the state highway department to repay the contractor for the additional cost.

By A. W. FRENCH & Co.

Chicago

Regarding finishing machines for different widths of road, our Ord concrete road surfacing machine is built in widths of 9 to 20 ft. and we have

a part which is standard for changing over from a 20-ft. machine down to 9-ft. machine.

Cement Production Returns 7.3 Per Cent on Investment

A return of 7.3 per cent on the total investment during 1922 is indicated by an analysis of the federal income tax statements of 11 of the principal Eastern cement companies producing 75 per cent of the cement manufactured in the Eastern states. This is the conclusion reached by H. Parker Willis, Professor of Banking at Columbia University, New York, to whom the companies submitted their operating figures for analysis and report. "It would appear," says Professor Willis, "that whether viewed as a return upon business turned over or upon the value of the output or as a return upon actual investment, the earnings of representative cement producers during 1922 have been well below the average obtained by industrial undertakings at large. The 11 companies under study materially reduced their prices during 1922, receiving on the average \$0.15257 less per barrel than in 1921. This figure represents the difference between an average 1921 price of \$1.75453 and a price for 1922 of \$1.60196."

For the 11 companies under consideration the output was 28,774,191 barrels or about 25 per cent of the entire production of the country as a whole. Gross sales of 11 companies, comprising both new and old products, were worth \$49,592,872. The aggregate net worth of the invested property of the concerns, as reported, was \$87,003,767. On the actual investment, Professor Willis states, the 11 mills have earned a total net income, after expenses and taxes, amounting to \$6,363,461 or an average return of about 7.3 per cent for the entire group. Total cash dividends declared during the year 1922 were \$2,278,634, or an average percentage slightly over 3.5 on a total capitalization of \$64,664,061.

The largest percentage of return, the report points out, is by no means obtained by the largest companies.

Fence Manufacturers Favor Simplified Standards

Eighty per cent of the manufacturers of farm, field, and poultry woven-wire fences of the United States, representing over 90 per cent of the country's annual production of that commodity, have signified their intention of accepting the simplified practice recommendation promulgated at the Commerce Department, July 11 and 12.

Woven wire fence manufacturers, distributors, and consumers, representing at least 85 per cent of the national capacity, met with W. A. Durgin, Chief of the Division of Simplified Practice, at the Department of Commerce, in July, in an effort to get together on some mutually satisfactory plan for eliminating excessive varieties of styles and containers existent in that industry. As a result, this conference recommended a reduction from 552 styles of woven wire fence to 69; and a reduction from 2,072 sized packages to 138. This means an 87.5 per cent elimination in the former, and a 93.4 per cent elimination in the latter.

Injunction Granted in Zeolite Water Softener Suit

The Permutit Company, New York, recently brought suit in the Federal Court in New York City against the Paige & Jones Chemical Co. for infringement of the Permutit company's patent covering zeolite water softening apparatus that had previously been sustained by the District Court at Buffalo and the Circuit Court of Appeals, New York. At a hearing in July in the Federal Court, New York City, Judge Learned Hand granted an injunction against the Paige & Jones Chemical Co. restraining it from further manufacturing or selling of infringing apparatus. The first suit in this patent, which was against the Refinite Co. of Omaha, Neb., was carried to the Supreme Court of the United States which denied a writ of certiorari to review it.

Business Notes

J. H. KEMPSTER has been appointed general superintendent of the Buffington plant of Universal Portland Cement Co. located at Buffington, Ind., succeeding the late C. O. Soderquist. This plant consists of mills No. 3, 4 and 6. In 1907, two years after graduation as chemical engineer from the University of Michigan, Mr. Kempster entered the service of the company as chemist of the plant at South Chicago. In 1908 he was appointed chemist of the Buffington plant and in 1915 was advanced to the superintendency of mills No. 3 and 4. Three years later he became superintendent of mill No. 6 which position he has held until his present appointment as General Superintendent of the Buffington plant.

JOHN F. CUNNINGHAM, JR., has been appointed assistant manager of the production department of the Schenectady works of the General Electric Co. In 1901, after a service of two years with the Hoosic Falls Power & Light Co. on power station and line work, he entered the employ of the General Electric Co. in the armature department. In 1906, he was transferred to the turbine section of the production department and later became assistant to the production manager, in charge of requisition service. In 1919, he was transferred to the works manager's office in the capacity of special representative.

Equipment and Materials

Light Portable Pump Driven by Air-Cooled Gas Engine

Weighing 780 lb. and with a capacity of 50 gal. per minute against a total head of from 30 to 35 ft., the portable pumping unit, manufactured by the Pennsylvania Pump & Compressor Co., Easton, Pa., is designed particularly for contractors' use in unwatering excavations, pumping out sewers and delivering a supply of water for concrete road construction. The pump, as shown in the accompanying illustration, is mounted on a four-wheeled hand truck. Power is furnished by a 5-hp. New Way air-

cooled gasoline engine, on the shaft of which is mounted directly a 3-in. centrifugal pump. The pump is of the single-stage side suction type with open impeller. The advantages of the air-cooled engine, the manufacturer points out, are its light weight, as compared with a water-jacketed cylinder, and the impossibility of trouble due to frozen

cylinders or clogged circulating pump or piping. That portion of the engine's shaft extending into the pump and exposed to the action of the liquid is covered with a bronze sleeve to prevent corrosion.

Water-Measuring Tank for Concrete Mixers

The new water-measuring tank, designed by The T. L. Smith Co., Milwaukee, for use on its concrete mixers and pavers, consists of an open-top trough, pivoted at both ends within the watertight outer shell of the tank. By tilting this trough at different angles, it is made to hold more or less water and in this way to regulate the amount of water that can be drawn from the tank. The action of this trough can be understood by taking up the operation of the tank, step by step:

Consider that the trough is in an upright position. The operator first allows water to run into the tank until it is full. Then he opens the valve at the bottom of the tank and allows the water to run out into the mixer drum.

The amount of water that runs out is equal to the tank full less the amount held in the trough. Tilting the trough so that it will retain less water permits more water to flow from the tank. When the trough is tilted to a position where it will no longer hold any water, the entire capacity of the tank can be drawn off.

A short arm at the end of the tank enables the operator to set the trough

in the position that will allow just the right amount of water to be drawn off for each batch. A graduated sector, along which this arm rotates, indicates the amount of water being used. A lock is provided to lock the arm at any point along the sector if desired.

The water enters and empties from the tank through a 24-in. valve located at the bottom of the tank. This large valve insures fast filling and emptying. The fact that the water is drawn off from the bottom also enables it to be emptied much faster than was possible with the old-style tanks from which the water had to be siphoned off.

In place of the usual three-way valve which was liable to damage by the grinding action of the dirt in the water, the new Smith tank is equipped with a piston-type, two-way valve. The piston operates horizontally and the seating surfaces, which are rubber and finished cast-iron, are in a vertical position. This makes it practically impossible for dirt to cling to the seating-surfaces because the incoming and outgoing water is continually washing them clean. Any dirt that may be caught in the valve will drop to the bottom of the valve housing where it can do no damage and from which it can be drained off occasionally through a small plug.

Publications from the Construction Industry

Concrete Floors—PORTLAND CEMENT ASSOCIATION, Chicago, has published a 16-p. pamphlet containing the American Concrete Institute's tentative standard specifications for concrete floors. The text covers materials, construction, plain and reinforced concrete floors, two-course and one-course floors and heavy duty floors for industrial buildings. Suggestions are offered for hardening and increasing the density of floor surfaces and coloring them.

Mechanical Snow Handling—BARBER-GREENE CO., Aurora, Ill., has just published a 20-p. illustrated pamphlet on the general subject of snow removal with particular reference to the use of mechanical equipment. General descriptions and operating data are presented for the company's new type of elevating snow loader which is now in service in a number of cities.

Concrete Mixers—FOOTE CONCRETE MACHINERY CO., Chicago, has issued a 24-p. illustrated pamphlet on its 14-E and 21-E crawler traction paving mixers. The text describes in detail the principal parts of this equipment including traction, frame, drum, power plant, loading skip, spreader bucket and power loading derrick. One page is devoted to the company's transport trailer for moving paving mixers rapidly from one job to another.

Concrete Mixers—T. L. SMITH CO., Milwaukee, is distributing a small folder descriptive of two of the Smith line of concrete mixers—the new 4-S tilter (half-bag) and the 7-S non-tilting mixer (full-bag). Special reference is made to the newly designed and much simplified device which is now used on the 7-S for operating the discharge chute.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Slight Change in Lumber Movement

Production of lumber in the United States, as reflected by 390 of the larger commercial sawmills of the country, was about the same for the week ending Aug. 18 as for the preceding week, says the National Lumber Manufacturers Association. Shipments showed an increase of about 3 per cent and new business a decrease of approximately 3 per cent. With 128 mills reporting as against 122 for the week before unfilled orders of West Coast mills increased from 305,893,356 to 325,860,186 ft., and 137 Southern Pine mills showed a decline in their order file from 231,411,399 to 223,839,786 ft.

For all the reporting mills, shipments were 85 per cent and orders were 76 per cent of actual production; for the Southern Pine Association mills these percentages were 94 and 85 and for the mills of the West Coast Lumbermen's Association, 89 and 84 per cent. Of the entire number of reporting mills, 359 reported normal production for the week, in relation to which actual production was 108 per cent; shipments 94 and orders 85 per cent.

For the first 33 weeks of 1923 and the corresponding weeks of 1922 the lumber movement of reporting mills was as follows:

	Production	Shipments	Orders
1923...	8,267,570,284	8,267,450,163	8,193,307,032
1922....	6,942,857,707	6,900,666,282	7,405,047,392
1923 Increase	1,324,712,577	1,386,783,881	788,259,660

Wholesale Prices Decrease

The index number of wholesale prices in the United States, compiled by the Federal Reserve Board for the purpose of international comparisons, decreased 5 points in July as compared with a decrease of 2 points in June. There were declines in all groups, Goods Produced falling 4 points; Goods Imported, 7 points; Goods Exported, 8 points; Raw Materials, 8 points; Producers' Goods, 4 points; and Consumers' Goods, 1 point.

INDEX NUMBERS OF WHOLESALE PRICES IN THE UNITED STATES
(1913 = 100)

	Goods Produced	Goods Imported	Goods Exported	Raw Materials	Producers' Goods	Consumers' Goods	All Commodities
1922:							
July.....	162	128	165	177	143	163	165
October....	161	135	163	179	150	156	165
1923:							
January.....	162	139	180	182	150	156	165
April.....	165	156	186	181	169	158	169
May.....	162	155	179	176	167	158	166
June.....	159	148	182	171	164	157	164
July.....	155	141	170	163	160	156	159

The index number is compiled from 100 wholesale price quotations for representative commodities taken in leading United States markets, weighted according to the importance of the commodity. Part of the quotations used are furnished by the Bureau of Labor Statistics, the rest are compiled from trade journals and private firms of recognized authority.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 129 to 142, are the following: Dam, Danville, Ky., to L. E. Meyer, Chicago, \$4,000,000.

Schools, Brooklyn, N. Y., to Lustbader Constr. Co. and G. A. Fuller, \$1,012,000 and \$2,492,000, respectively. Gas container, Milwaukee, Wis., to Riter-Conley Co., Pittsburgh, Pa., \$1,500,000.

Bank and office building, Miami, Fla., to R. C. Miller and Ingalls Iron Works, Birmingham, \$1,500,000.

Schools, New York, N. Y., to T. A. Clark Co., Brooklyn, P. J. Brennan & Son and Frymier & Hana Co., Inc., \$937,700, \$1,054,000 and \$905,480, respectively.

Bank and office building, Cleveland, O., to Hunkin-Conkey Constr. Co., \$1,000,000.

Apartment, Long Beach, Calif., to Ransford-Goble Co., Los Angeles, \$1,000,000.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 129 to 142, are the following:

Bridge, Jacksonville, Fla., for Florida East Coast Ry., St. Augustine, \$1,800,000.

Bank and office building, Pasadena, Calif., for Pacific Southwest Trust & Savings Bank, \$1,300,000.

Freight Loadings Continue Heavy

Loading of revenue freight, according to the Car Service Division of the American Railway Association, continues to run the heaviest for this time of year in the history of the United States. From Jan. 1 this year until Aug. 18, inclusive, (a period of 33 weeks) 30,999,244 cars were loaded with revenue freight. This is the largest number loaded during any corresponding period in history, exceeding by 5,195,251 cars the corresponding period last year, and by 6,904,844 cars the corresponding period in 1921.

For the week ended Aug. 18, 1,035,741

cars were loaded, the second highest total for any one week in history. This was only 5,303 cars under the record week of July 28, when, 1,041,044 cars were loaded. Compared with the corresponding week last year, this was an increase of 189,475 cars or 22.4 per cent, while it also was an increase of 220,594 cars over the corresponding week in 1921.

Value of August Contracts Nearly Twelve Per Cent Under Same Month Last Year

Total of 820 Awards During August, Average Value \$172,681 Compared With 755 in July, Averaging \$216,502

Contracts awarded in the five issues of *Engineering News-Record* during August totaled \$141,599,000 as compared with \$163,459,000 in the four issues of July. This represents an average weekly value of \$28,319,800 for August, against \$40,864,750 during the preceding month.

The weekly average of \$28,319,000 for the month of August represents a decrease in money value of 12½ per cent below the weekly average for the corresponding period in 1922. August 1922 contracts totaled \$160,130,000.

The number of awards totaled 820 during August, with an average value of \$172,681 as compared with 755 in July, averaging \$216,502.

Mini. um costs observed in *Construction News* on each class of construction are as follows: Water-works, \$15,000; other public works, \$25,000; industrial construction, \$40,000 and commercial buildings, \$150,000.

Of the \$141,599,000 a total of \$13,442,000 represented Canadian awards, which gained slightly over the July lettings.

All classes of construction fell off during August except industrial works and sewers. August sewer contracts more than doubled those of July, in total money value, and industrial works gained over 25 per cent during the month.

Among the large industrial projects awarded during August were the following: hydro-electric power plant at Island Portage, Ont., \$4,000,000 to \$5,000,000; a cement plant at Ft. Worth, Tex., \$1,000,000; an addition to a cement plant at Bonner Springs, Kan., \$1,000,000. The largest sewer contract involved the construction of sewage treatment works at Chicago, Ill., \$5,602,636.

The actual physical volume of construction represented by August contracts is 28 per cent less than August, 1922, and 5 per cent under 1921, but 37 per cent heavier than August, 1920.

Engineering News-Record Construction Cost Index Number

September, 1923	221.50
August, 1923	221.50
September, 1922	185.00
Peak, June, 1920	273.80
1913	100.00

Engineering News-Record's Construction Cost Index Number, 221.50, for September, is exactly the same as for the preceding month. Prices of basic building materials remained unchanged during the month. The average rate for common labor is still 54c. Thus, general construction cost is 20 per cent higher than, one year ago and 19 per cent under the peak; it is 121 per cent above the 1913 level.

Engineering News-Record Construction Volume Index Number

Monthly	
August, 1923 (5 issues of E.N.R.)	111
July, 1923 (4 issues of E.N.R.)	128
August, 1922 (5 issues of E.N.R.)	154
1913	100
Yearly	
1922 (entire year)	130
1921 (entire year)	88
1920 (entire year)	91
1913	100

Engineering News-Record's Construction Volume Index Number is 111 for the month of August, and 130 for the whole of 1922, as against 100 for 1913. This means that the actual volume of construction in 1922 (not the mere money-value of the contracts let that year) is 30 per cent above the volume of construction for 1913. Our monthly volume number, 111 for August, 1923, is really the increment of construction, and indicates the rate at which contracts are being let as compared with 1913 awards.

VALUE OF CONTRACTS LET IN THE UNITED STATES AND CANADA DURING AUGUST, 1923

	New England	Middle Atlantic	Southern	Middle West	West of Mississippi	Western	Total United States	Canada	Total
Water-works	\$135,000	\$208,000	\$152,000	\$1,648,000	\$1,012,000	\$42,000	\$3,197,000	\$481,000	\$3,678,000
Sewers		2,194,000	455,000	7,617,000	595,000	2,743,000	13,604,000	149,000	13,753,000
Bridges	102,000	1,049,000	672,000	1,617,000	308,000	50,000	4,248,000		4,248,000
Excavation, drainage and irrigation			108,000	322,000	916,000	991,000	2,337,000		2,337,000

August, 1923	\$4,308,000	\$30,933,000	\$11,974,000	\$34,425,000	\$24,962,000	\$21,555,000	\$128,157,000	\$13,442,000	\$141,599,000
July, 1923	\$3,897,000	\$44,631,000	\$24,065,000	\$42,044,000	\$25,666,000	\$19,718,000	\$155,023,000	\$4,436,000	\$163,459,000
June, 1923	\$0,193,000	\$43,357,000	\$15,373,000	\$58,783,000	\$29,945,000	\$20,936,000	\$178,587,000	\$10,199,000	\$188,786,000
Total 3 months	\$23,398,000	\$108,923,000	\$51,412,000	\$135,232,000	\$80,573,000	\$62,209,000	\$461,767,000	\$32,077,000	\$93,484,000

Labor Rates and Conditions Throughout the Country

Continued advances in cost of food and clothing and further increases in rents, during the period between June 15 and July 15, 1923, resulted in an increase of 1.1 per cent in the cost of living throughout the country, according to reports of the National Industrial Conference Board. Living costs on July 15, of the current year, were 61.9 per cent higher than in July, 1914. Fuel prices, however, were a trifle lower, while average sundries and light charges remained unchanged.

Wage changes in the United States during the month ended Aug. 14, 1923, totaled seventy-seven, all of which were

increases. The wage advances occurred as follows: Printing industry, 27; railroads, 14; building trades, 10; metal working trades, 8; street railways, 6 and miscellaneous industries, 12.

The average rate paid common laborers, pick and shovel men in construction operations, remains at 54c., the same as for July and August as against 53c. per hr. during June, according to *Engineering News-Record* figures. Local building conditions are as follows:

Baltimore—Conditions easing up in employment of carpenters, bricklayers and hodcarriers. Hoisting engineers

advanced 10¢ at 12½c.; common laborers, 10c. per hr.

Birmingham—Plasterers increased from \$1 to \$1.25 per hr.

Boston—Scarcity of bricklayers and hodcarriers; attracted to other cities by higher wage rates. Hoisting engineers' rate at maximum of \$1.35, against \$1.25 per hr. formerly.

Chicago—Three of the largest building constructors in Chicago have withdrawn from the Landis Award Committee and begun to unionize their work.

Dallas—Increased demand for bricklayers and carpenters; building active.

Detroit—Masons and plasterers in

good demand. Conditions normal in all trades.

Kansas City—Structural iron workers now receiving \$1.07½; will demand \$1.25 per hr., effective Sept. 1.

Los Angeles—All building crafts busy; no labor shortage.

Montreal—Scarcity of carpenters, bricklayers and hodcarriers; other crafts ample.

New Orleans—Carpenters' strike still on, but effect on construction is negligible. Bricklayers granted increase of 25c. and structural iron workers, 10c. per hr. Strike of metal workers

threatened Sept. 1.

New York—Base pay for carpenters \$9, with bonus of \$1 per day, effective June 1. Cement and concrete laborers \$6.50, with bonus of \$1 per day, effective July 16. Hoisting engineers' base wage \$10, but when employed on jobs where bricklayers are working, both receive same rate.

Philadelphia—Situation easier with bricklayers; over-supply of carpenters. Plenty of other trades. No employment for pile drivers at present.

Pittsburgh—Scarcity of bricklayers; plenty of other crafts. Change from

12-hr. to 8-hr. shifts in steel mills will result in wage advance of about 25 per cent. Several thousand additional workers will be required under the new schedule.

St. Louis—Bricklayers will demand \$1.75 per hr. after Nov. 1. Many being paid \$14@15 per day at present. Carpenters' scale to be \$1.50, effective Oct. 1. Decided slackening in demand for building trades mechanics due to falling off in new projects. Surplus of workers noticeable in some crafts.

San Francisco—Building trades mechanics busy despite slow-down.

Monthly Prices of Construction Materials

Ups and Downs of the Market

Pig Iron—Market spotty. Sales reported as low as \$24 per ton at Birmingham for No. 2 foundry; \$27 demanded on small lots for immediate delivery, against \$25, one month ago. August business heaviest since spring. Furnaces facing higher fuel costs; spot coke market up.

Railway Supplies—Heavy buying movement developed in steel rails, which form the largest item in steel exports. Railway ties tending higher. Fairly active demand for railroad equipment; prices firm.

Pipe—No changes in prices of wrought steel and iron pipe; demand improved. Cast-iron pipe higher in New York. Sewerpipe lower at Pittsburgh; advanced in Kansas City and Boston.

Road and Paving Materials—Asphalt, package and in bulk, advanced in Boston and declined in Cincinnati, during month. Granite paving blocks up \$4.75 per M. in Montreal; down \$2 in Boston. Wood blocks also declined in Boston, 10c. per sq.yd.

Sand, Gravel and Crushed Stone—Gravel, ¾-in., dropped 10c. in Boston and 25c. per cu.yd. in Los Angeles.

Sand, however, advanced 10c. per ton in Cincinnati. Crushed stone, ¾-in., up 30c. in St. Louis and 33c. per cu.yd. in Dallas due to freight and labor adjustments; down 25c. in Los Angeles and 10c. per ton in Boston, during month.

Lime—Hydrated finishing, up 50c.; common, \$1 per ton in Boston; lump, finishing and common, advanced 15c. per bbl. Los Angeles reports drop in common lump.

Cement—St. Louis reports advance of 10c. and Atlanta, 15c. per bbl. during the month. New Orleans, however, dropped 40c. Prices prevailing in Chicago, Detroit, Indianapolis, Milwaukee, Pittsburgh and two or three other points are the same as those in effect one year ago.

Structural Steel—August steel business slower than for any previous month since October, 1921. Prices firm despite dullness of market. Inquiries for steel plates and shapes plentiful, but mills finding difficulties in meeting delivery specifications. Plates and shapes firm at \$2.50 per 100 lb., f.o.b. mill. Demand for shapes mostly in small lots. Bars firm at \$2.40, with demand improving.

Brick and Hollow Tile—Common

brick, \$20 per M., alongside dock, New York, against \$21@22, one month ago and \$18@20, one year ago. Decline of 50c. per M. reported in Los Angeles and Detroit. Boston, however, quotes rise of \$1. Hollow tile down in New York and St. Louis; higher in Los Angeles.

Lumber—Demand slack, due to seasonal dullness. Production and shipments low; stocks large; plenty of cars. August market weaker than preceding month. Price declines reported in San Francisco, Chicago, Boston, Minneapolis, Kansas City, Detroit, and St. Louis. Denver, however, quotes advances in fir and hemlock.

Explosives—Dynamite, 40 per cent gelatin, up in Boston and St. Louis; down in Kansas City; 60 per cent, higher in Boston and lower in Kansas City.

Scrap—Iron and steel scrap higher than month ago in New York and St. Louis, particularly in heavy melting steel. Market firm with increase in fuel prices.

Linseed Oil—Raw oil dropped 9c. in New York and 14c. per gal. in Chicago since Aug. 1. Declines reported in Atlanta, Minneapolis and San Francisco.

Price advances since last month are indicated by heavy type; declines by italics

PIG IRON—Per Gross Ton—Quotations compiled by The Matthew Addy Co.

Cleveland.....	.29	St. Paul.....	.32
Denver.....	.215	St. Louis.....	.43
	1.27	St. Paul.....	.60

* Minimum carload, 40,000 lb.

* Minimum carload, 50,000 lb., structural steel only; 80,000 lb., for other iron or steel products.

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

E. J. MEHRIN, Editor
FRANK C. WIGHT, Managing Editor

Volume 91

NEW YORK, SEPTEMBER 13, 1923

Number 11

Structures and the Japanese Earthquake

LITTLE reassurance has come from Japan in the fragmentary bits of news that have drifted in since the first word of the earthquake of Sept. 1. A stupendous total of death and destruction is sure, even though the unavoidable exaggeration of first estimates has been slightly discounted. But there is somewhat better assurance than was available a week ago that the steel-frame and concrete buildings in the devastated area were not destroyed, as early rumors asserted, but survived substantially intact, as they did in San Francisco. This is at least an item of satisfaction, small though it be when measured in the total. It is now more certain too, that the violence of the movement was phenomenally great. Much is to be learned, therefore, from the effects of the earthquake in relation to safe construction, for the benefit of future generations. The full story of the engineering aspects of the disaster, however, will doubtless come only after weeks or months.

An Expedient Settlement

BY THE terms of the anthracite coal settlement the miners gain a horizontal raise in wages, the operators prevent the check-off and lose no part of their profits, the State of Pennsylvania will gain close to a million dollars extra taxes on coal exports, and the public will have to pay more for its coal. It is easy, therefore, to figure out who wins by the settlement. The best that can be said is that in all probability anthracite coal disputes have been prevented for another two years, at a cost to the citizen's purse. The proposed investigation of freight rates and middlemen's profits may result in an absorption of some of the increased cost before it reaches the consumer but the possibility is remote. Governor Pinchot can hardly be blamed for making expediency the governing element in the agreement. By the time the dispute reached him there was probably no other way out. The fact remains that the horizontal wage raise is inequitable, even admitting that some of the miners are entitled to more pay, and that the whole fabric of the cost of coal to the consumer is so complicated that it needs radical readjustment by some other method than making the user pay more. The result of the strike and the agreement is disappointment that the strike of last year and the organization of the Federal Coal Commission have produced such meager results.

Six Examples

THE value of underground water-waste surveys is forcibly illustrated by the six examples of leaks thus detected at Detroit that fill a page of this issue. These six leaks alone were wasting water at the rate of 6.8 m.g.d., while other underground leaks found by the pitometer brought the total to nearly 10 m.g.d. Even

more leakage of other sorts was located by the water-waste survey, bringing the total to a saving of 24 gal. per capita. If so much can be done where 98½ per cent of the taps are metered what would similar efforts do in some of our cities with practically no meters in use and no reliable knowledge of what leaks and other wastes are occurring daily?

An Engineer Wins a Prize

FOR some time we have been contending editorially what too few engineers seem to have taken seriously—that the engineer is the logical person for the solution of our greatest municipal problem, the growing congestion of traffic in our city streets. We are pleased to record one instance in confirmation of the contention. Some weeks ago some theatrical interests in New York City, concerned no doubt at the prospective loss of business from the difficulty of gaining access to their doors, offered substantial prizes for the best solutions of the traffic problem in the metropolis. A committee—on which there was no engineer—has just awarded the first prize of \$1,000 to Arthur S. Tuttle, the chief engineer of the Board of Estimate of the city. The details of the award are given in the news pages of this issue. We congratulate Mr. Tuttle on having demonstrated to some of the people of New York, at least, that this is a subject on which an engineer's views are worth while.

Mobile Construction Equipment

MANUFACTURERS are making long strides in producing mobile construction equipment. The contractor is no longer satisfied by merely putting wheels under a machine or even by low-geared self-propulsion; he demands speed of travel and manoeuvring ability. Where he cannot get these practicably by self-propulsion he is calling in the motor truck and fast tractor and requiring his concrete mixers and other machines to be provided with running gear for fast hauling or so arranged that they can be speedily loaded and unloaded for truck or trailer transportation. The railways originated the demand for such equipment, the street railways followed with its development to a remarkable degree and now highway work and general contracting are becoming insistent in their demand. It is also the contractor doing many small jobs and not particularly the contractor for large operations who most wants highly mobile equipment. It enables him to use machines for many tasks for which, if much time were required to move machines, it would be necessary to use men. An equally important gain which is coming to be appreciated is that it enables the economy of large capacity equipment to be extended to small operations. For scattered jobs of yard paving and commercial garage floors, for example, time enough is saved by a 21-E paving mixer, if it can be shipped quickly, to increase materially the volume of work a contractor

can handle. This is not speculation. There are contractors who are successfully using these large machines for scattered small paving operations. Outfits are known where a 21-E paver is loaded onto a motor truck trailer in 15 minutes; at its destination it is unloaded and at work in another 15 minutes. The move from job to job is made at a speed of eight to ten miles an hour. These developments are making the large machine an economic factor in small job contracting which deserves further study. Similar opportunities exist in other fields than paving, such as water-works and sewer extensions and repairs, to name only two examples.

The Berlin Deferrization Plant

THE Berlin iron- and manganese-removal plant described in this issue is interesting both in itself and because it brings to engineers outside of Germany an account of how Berlin handled a problem of this sort just before the war. It appears that the Berlin capital, which for years had been removing iron from its water supply by aeration and slow sand filtration, fell into line with the strong trend of American practice some ten years ago and for the plant completed in 1914 substituted rapid or mechanical for slow sand filters. The impinging jet aerators, the prefilters and final filters, both in arrangement and details, have notable features. Both sets of filters are operated at high rates. The injector wash for the final filters, used only after the ordinary reverse-flow and compressed-air wash becomes inefficient, brings to mind the ejectors in the drifting sand filters at Toronto. The doubling of the iron content of the water at Berlin in six years is in general line with what must often be reckoned with in underground water supplies. Finally, the architectural attractiveness of the buildings that house the plant may be noted as a feature worthy of emulation in this country, although it is a pleasure to be able to say that a goodly number of American cities are not unmindful of the fact that good architecture is a municipal asset even in utilitarian buildings.

Roadbuilding a Market for Steel

RARELY is thought taken of the steel maker as a materials producer for road construction. Yet in 1921, according to the Bureau of Public Roads, 2.1 per cent of the money spent for federal-aid roads was spent for reinforcing steel for concrete pavement and structures. As about \$112,325,000 were put into federal-aid roads in the year named, the cost of reinforcing steel was about \$2,376,000 or some \$318 per mile for the 7,480 miles constructed. In round figures about 10,000 miles of new road of the first class has come to be our annual production. When to the reinforcing steel for this mileage we add the steel for road signs and guard rails, for steel bridges and for the equipment employed in building roads there is had a rather impressive sum represented, by the products of the steel maker, in highway construction. This is a continuing market. The federal-aid program alone contemplates 187,000 miles of highway of which over 160,000 miles are still to be constructed and federal-aid road is not over half of the mileage of state trunk-line roads that have been planned for construction. Roadbuilding has become an important factor in the metal-working industries.

Dangerous Warning Signs

PROPER warning signs, we all know, prevent accidents and promote safety. But improper or unnecessary warnings are positively dangerous. Some highway warning signs are of this kind, and give daily evidence of a need for revising and establishing consistent practice in the system of posting danger spots on roads. The sign "Danger—Sharp Curve" posted at a moderate bend misleads more than it warns; repeated, it produces disregard of all curve warnings or, worse still, it brings on sudden disaster when the driver comes to a sharp curve which by chance has the warning sign omitted altogether. Similarly, the important safety warning "Narrow bridge" becomes a danger when used needlessly. So long as narrow bridges, sharp curves and dangerous crossings continue to exist on roads and high-speed transportation is demanded, warning signals will be increasingly important. The highway art is yet young in respect to thorough signaling, but the demands of the day nevertheless call for early and well-considered development of good practice.

Efficiency Rather Than Politics

AN ENGINEER, in the person of Col. Frederick Stuart Greene, has been appointed by the governor as head of New York State's Department of Public Works, which has just come into being in accordance with the provisions of the state reorganization act which took effect July 1. The post is an important one, both politically and technically. While it could readily be assumed by a politically minded official to be anything but an engineering position it involves the administration of such engineering works as highways, bridges, public buildings, waterways and canals. The very nature and scope of the department's activities necessitate the spending of large sums of money and the filling of a long list of jobs, so that from the point of view of party patronage the superintendent of public works of New York State is in the position of being able to dispense many favors. It is natural to suppose that great pressure must have been brought upon the governor to appoint as head of this new department a man who could be relied upon to "do the right thing" by the job-seekers of the party in power. Yet Governor Alfred E. Smith, himself the choice of Tammany Hall, has had both the wisdom and the courage to select his superintendent of public works on the basis of administrative and technical fitness for the job in hand rather than upon that of political expediency. Colonel Greene is an engineer of wide experience, a member of the American Society of Civil Engineers, a former New York State highway commissioner, and, during the war, the commanding officer of a combat engineer regiment in the 77th Division. Appointments of this sort go a long way toward raising public officials to a new plane of respect in the minds of the electorate. If more governors of states and mayors of cities would follow Governor Smith's example of appointing properly qualified engineers to managerial jobs, it is certain that the taxpayers would reap untold benefits in the form of better and less costly public works. Incidentally, the Governor of New York might well read the Secretary of the Interior a lesson on how politics may be eliminated in the conduct of public office, especially where engineering service is the main work which is to be administered by the department head.

Elementary Road Types Not Overlooked

ELEMENTARY road types—earth, gravel, macadam—astonish us often with their ability to carry traffic satisfactorily, even traffic of modern swiftness and volume, when scrupulous care has been given to detail in construction and when the maintenance is continuous and thorough. Such construction and maintenance were the requirements set forth as invariably necessary for good road service in the first textbooks on roadbuilding written when no other than the simpler types were contemplated for rural traffic; they also were the requirements usually realized in the roadwork of England and France and very seldom realized then in the roadwork of America. In coming back from his survey of roads in the Far East, with the same thought outstanding, Colonel Crosby does not offer us a new lesson in what he says on another page; he but repeats an old one in danger of being forgotten, he feels, in our present epoch of paved roads and of motor-bus and truck traffic.

This reminder is good for us. We accept it appreciatively from a veteran road builder knowing that he does not mean to be taken quite literally in calling quantity production our golden calf and "permanent roads" a will o' the wisp.

There is found, indeed, when we come to examine the facts, much less variance than might be anticipated between Colonel Crosby's implied thought and present American roadbuilding practice. "Permanent roads" have been emphasized in the talk of engineer and layman alike until it has seemed that paved road construction predominated in the improved road mileages of recent years instead of being only a small fraction of the total improved road and an almost infinitesimal fraction of the total road.

Of about 25,000 miles of road improved with federal aid 27 per cent are paved roads. All the remaining mileage is road of the elementary types, largely earth, gravel and macadam. Generally, too, federal aid goes only to the main trunk-line state roads. If improved roads of all classes were taken, it is shown by the few state highway censuses available, the ratio of paved roads to other improved roads would be still smaller.

There is scant evidence in either statistics or observation that the highway engineers of the United States are forgetful of the truth that for years to come it will be good economics to build more miles of roads of simple types than of concrete and asphalt and brick. Indeed if any alarm is to be felt it is because at the present moment some of the major roadbuilding states are showing an inclination to swing too strongly toward other than paved road construction. Less comfort is got from the situation when maintenance of the kind thought of by Colonel Crosby is given consideration. We have too little of it. Yet in some states maintenance is very good and every year it is getting better in more states.

Parallel conditions in roadbuilding do not prevail in the Orient and in America and Colonel Crosby never assumes that they do. His thought is merely that in America, due to carelessness in construction and, chiefly, to neglect of upkeep, we do not get the quality of traffic service from our roads of the elementary types which is being obtained in countries where road improvement procedure is comparatively primitive. He is correct. This carelessness in building and maintenance, however, is more a tradition of the past than

a practice of the present. Our earth and gravel roads of today's construction are radically different structures from those of twenty years ago and they are being kept up in a way that they never were before.

It is quite worth while to stress these facts because it is getting to be too complacently assumed by too many that highway engineers are running wild in paved road construction to the neglect of the simpler types which must for a long time constitute the majority mileage of our rural highways. Consequently we are having such occurrences as the recent actions of the politician governors of Ohio and Michigan in usurping the technical direction of highway development. American highway engineers may not have sensed everywhere at all times the controlling problems of highway development, but it is certain that there is no group of men having a better grasp of all the factors that enter into the creation of a great highway transportation system. It is important that this truth should be spread before the people.

Laymen Water Bacteria Hunters

IN CALIFORNIA the State Board of Health is advocating the establishment of laboratories in small towns to check bacterial reduction due to chlorination or other water treatment, even where trained bacteriologists are not employed. More or less similar efforts have been made by the health departments of several other states. The equipment for a "minimum" laboratory under the California plan, as itemized in our issue of Sept. 6, p. 401, would cost about \$135, which is certainly well within the financial capacity of any water-works plant, however small.

The serious question that arises is whether the ordinary operator can be trained by a state health department or otherwise to make even the simplest bacterial tests. Of minor moment but worth consideration is the effect upon trained operators, if they must compete with the relatively untrained operators in charge of these "minimum" laboratories. The argument is that the "minimum" laboratories are simple and are put in only where the employment of an experienced laboratory man is entirely outside the financial capacity of the town. Would it be better, where one town cannot afford the full time of a trained operator, for a state health department to urge that two or three or more communities within reasonable distance of each other combine in the employment of a trained man? In some states, at least, water testing could be combined with other laboratory work for health protection, either in county or other district laboratories.

In considering this matter account should be taken of the false sense of security which may be created in a community relying on the work of the tyro in making bacterial media, maintaining sterile apparatus and taking and plating samples.

At the same time, conditions may exist in some if not in most states where the choice in many communities is between state health board efforts to bring training to the layman filtration or chlorination plant operator on the one hand or on the other to leave the plants in question in the charge of men ignorant of what constitutes safe drinking water and even more ignorant of the simplest means of testing it. Broadly, the staff of a state board or department of health is better fitted than any outsiders to choose a plan best suited to conditions within its own borders.

Failure of Apishapa Earth Dam in Colorado—II

Two Independent Reports Written After Investigations and Interviews at Site Agree that Failure Was Due to Conditions in Body of Earth Fill

The first report attributes the failure to poor material badly placed and compacted, resulting in settlement, caverns and saturation, with final burst of water diagonally through the top portion of the dam. Conclusions of the second report absolve all concerned from carelessness or slighted work and attribute the failure to unequal settlement due to

bottom subsidence and movement, without stating the primary cause. The second report points out some elements of weakness which the authors do not think had anything to do with the failure. Preliminary reports by the same authors appeared in *Engineering News-Record*, Sept. 30, p. 357.—EDITOR.

Sequence of Events and Their Causes

By JOHN E. FIELD

Consulting and Supervising Engineer, Denver, Colo.

AT ABOUT 3 p.m. on Aug. 22, a flood occurred in the Arkansas Valley of Colorado which constitutes, next to the great flood in the same valley in 1921, the greatest disaster that has befallen any agricultural community in the state. Considering the many irrigation works, their value, and the long period from 1860 to date that irrigation has been practiced, the comparative immunity from serious losses through failure of the irrigation works is remarkable. At the hour

sides to the crest of the dam. These portions of the structure have, so far as ascertainable, remained intact, as have also the outlet works, tower and tunnel.

The volume of fill in the dam is given as around 315,000 cu.yd., practically all of which was washed away. The water face was in part protected by rock riprap, which, however, did not reach to high-water level but remained uncompleted for some 20 ft. vertically below high water.

The reader is referred to the issue of *Engineering News-Record*, June 16, 1921, p. 1030, for a more detailed description of the dam and to p. 357 of the Aug. 30, 1923, issue for a cross-section of the dam and preliminary reports on its failure.

The material forming the lower layers of the dam, constituting, according to report, about half the total yardage, was taken from the bed of the reservoir above the dam and about one-fourth mile distant. The upper portion was of material taken from the mesa east of the canyon, also about one-fourth mile away. The plans called for selected material in the upstream four-fifths of the dam, but there appeared to be little difference between that portion and the downstream fifth. An examination of the plans shows that they were well conceived and that the work on the foundation, cutoff walls, etc., was excellent.

The material is fine sand with some cementing material. When wet it becomes very soft, though when shaken up with water in a vessel it settles to comparative clearness in a few minutes. When dried it becomes very hard and forms into lumps which are hard to break with the hand and into which an oak survey stake is driven with difficulty. To those familiar with western soils the description would be a light sandy soil with alkali.

Test of Soil from Dam—A sample treated with water for two hours resulted in a loss by weight of nearly 6 per cent. When treated with weak (5 per cent) hydrochloric acid, there was a strong effervescence, carbonate of lime and magnesium probably being the principal solubles in this case. The portion treated first with water and then with the acid showed a loss of 4 per cent in the acid treatment, and a combined loss of 10 per cent. The sample used was from the lower slope from a hole or cave-in which will be mentioned later. The sample is fairly typical of that taken from the borrow pits on the mesa.

In 1921 the maximum storage in the reservoir at any one time was 9,770 acre-ft., or a gage height of 65; the zero point being the lip of the inlet-well to the tunnel, or El. 4840 on the drawings. In the winter of

Photograph from Barton M. Jones and O. N. Floyd

FIG. 1—GAP IN APISHAPA EARTH DAM CAUSED BY FAILURE ON AUG. 22

Looking north downstream. Each end of dam, with concrete cutoff walls built into abutting canyon sides, left standing; no damage done to the outlet tower at left or west end of dam.

stated, the large earth dam on Apishapa Creek, some forty miles southeast of the town of Pueblo, failed.

At the time, the reservoir was practically full, the water being 1.1 ft. below the spillway level and about 10 ft. below the crest of the dam. The reservoir has an area of 640 acres and contained 18,500 acre-ft. of water. Briefly, the dam was 115 ft. high above river bed, 536 ft. long at crest, with 2 to 1 slopes on the lower and 3 to 1 on the upper side, and was located in a box canyon. The spillway was about one mile east from the dam.

Dwarf Cutoff Wall—Steel sheetpiling had been driven into the foundation to bedrock, surmounted by timber sheetpiling to the approximate level of the original ground forming the floor of the canyon. This sheetpiling terminated in concrete cutoff or baffle walls at each side of the canyon, which baffles extended up the

1921-22, 5,000 acre-ft. of water was carried over. This was used in 1922. The reservoir was dry during the winter of 1922-23.

Storage in the reservoir began in the spring and reached a gage height of 66, when some water was withdrawn; it was again allowed to rise, this time to a gage height of 76, where it stood until Tuesday, Aug. 20, when it began to rise still more. The valves were at full opening for sixteen hours prior to the break, discharging at an estimated rate of 2,500 sec.-ft. The rains and cloudburst caused the water to rise and fall somewhat until the 23rd, when an unusual rain caused such a rise in the Apishapa that the water rose in the reservoir to gage 83.1 ft. at 3 p.m., Aug. 23. The spillway level is about gage 84.2 (El. 4424.2), though there is a small channel a fraction of a foot lower.

The Failure—There were at the dam during the week of the failure about thirty men, including Mr. Knowlton, an engineer-contractor and a landowner in the project, and Mr. Dallimore, the engineer of the system. These men were being employed in miscellaneous work but particularly in repairing a small leak near the west end of the dam and in filling in some settlement areas and cracks near the point marked B on the plan shown herewith.

At 2:45 p.m., the repairs on the leak were about completed and the leak at this point was stopped. Mr. Knowlton had walked across the dam at about 1 o'clock, carefully observing the dam crest, and down to the water edge to see if any additional cracks had started or any settling or subsidence. None were observed by him, and except where the repairs had been made there was no apparent danger.

At 2:45 Mr. Dallimore made a trip of inspection and observed a settlement at the water edge at a point about 100 ft. west of the east end of the dam (Point A of the plan). Water was running into the settled area and apparently passing downward into the body of the dam. He called for his workmen, who started to try to stop the break.

At the same time or a few minutes after the break was first observed, water began to appear on the lower slope some 500 ft. west and 30 ft. below the crest. This point [B on plan] was about 60 ft. east of the point where repairs had been in progress. Almost immediately after the leak on the lower side was observed, wet spots appeared on the lower slope, first a short distance east of the break on the lower slope, and then in rapid succession wet spots appeared further to the east, each a little higher in the slope than the last. The flowing water rapidly ate back on the fill diagonally up the lower face of the dam and finally to a point immediately opposite the first observed break in the water side. Desperate efforts to choke the break were made by the workmen; among other things a galvanized steel tank 6 ft. in diameter and 20 ft. long was rolled into the hole. It held but an instant and passed through the hole. It is apparent the dam was doomed from the moment water began to flow in the lower side.

Cavities in Top of Dam Before Failure—An examination of the hole where the repairs were being made showed it to have been a cavity shaped like a beehive, the material near the surface being arched over. No distinct line of saturation was observable on the two

ends of the dam as they were left after the break. The material was very dry. The laminations of the fill were distinct and approximately horizontal. Whether the material in the base of the dam was different from that above was not observable, as the portions remaining were above the edge of the cliff walls and less than one-half of the height of the dam. The wet area on the section of the dam remaining appeared from about gage 65 on the water face and sloped downward at an angle of about 30 deg. to the cutoff wall. Below the center line none of the material seemed to be wet from causes other than from the out-rushing water at the time of the break. On the westerly end in particular no line of saturation was observable, leading to the conclusion that the cavities did not have water in them for any considerable length of time, and if they filled it was during the period when the water rose from gage height 76 to 83.

The cavities apparently extended from near point A some distance within the dam from the upper slope diagonally across the center line to a point nearly 400 ft. westerly, where the water broke through the lower slope. The cavities were doubtless connected by a longitudinal crack as the break on the upper face was followed within a few minutes by the appearance of flowing water on the lower face.

At the A. T. & S. F. railroad bridge the discharge of the Apishapa was about 60,000 sec.-ft., from 10:45 p.m. to 1 a.m., and the river was again within its channel at 9 a.m., Aug. 24.

The principal damage below the reservoir was to headgates and dams in the Arkansas River, though even at the Catlin dam, which is just below the mouth of the Apishapa, the water did not reach the 1921 flood height by 3 ft., and at La Junta was reported as not within 15 ft. of the 1921 flood height. The headgates of the Holbrook and Fort Lyons storage intake canals were destroyed. There were many minor cases of damage, such as to the railroad bridge and embankment, the state highway and bridge, the west half of which, an old pile structure, was entirely destroyed by the flood.

Cause of Failure—The results of the observations of the writer lead him to conclude that the material was unsuitable for an earth fill, especially for the upper face; that sufficient water in puddling and rolling was not used, and that the thickness of the layers of the fill [previously reported as 12 in.] was too great. These things resulted in a considerable settlement in the dam not observable on the surface, and a cavernous condition at about 30 ft. below the crest. When the water rose in the reservoir above gage 76, the caverns filled and the adjacent earth became saturated with water, and when the water rose to gage 83 the hydrostatic pressure on the outside of the upper slope and inside of the lower slope was too great to be held by the shell arching the caverns or forming the walls of the crack and faulting planes.

Where a dam in whole or in part remains dry and untouched by water for even a year in the dry air of the arid west, sudden filling of the reservoir is dangerous. Within the experience of the writer several dams have failed at or within a few hours of the first filling, after there had been ample time for the dam to dry out in its upper and thinner section. In two of the cases a considerable percentage of solubles was in the fill mate-

rial. Particulars [sent by wire at our request—EDITOR] follow:

Lyman Dam, Arizona, failed the day after the first filling on account of poor material and construction in the closure section. Solubles were present in this material.

Terrace Dam almost failed. Its upper part was wagon fill. This dried, settled and cracked, permitting water to reach sand layers below, placed by hydraulic sluicing.

Antlers Dam failed in 1899 after a hole had formed similar to the one in the Apishapa dam. The Antlers Dam had been raised and failed shortly after first filling.

Jumbo and Horse Creek dams failed by piping [?] on shallow bedrock before they had been in full use more than a year.

Dry Creek Dam, 15 ft. high, failed at the first filling. It had gone through one summer empty.

Photographs from Messrs. B. & O. Co.

Unequal settlement due to varying heights, especially where there are abrupt changes in profile, cause shearing planes. These remain open while the fill is dry but when the water rises suddenly it flows along the shearing planes.

Every earth dam should be regularly inspected by competent observers, and the inspection should not be left to the watchman or to any one other than the engineering force.

Further Report on Apishapa Dam Failure

By BARTON M. JONES AND O. N. FLOYD

Engineers with the Dayton Morgan Engineering Co.,
Pueblo, Colo.

A BRIEF account of the failure of this dam was given by the authors of this article in *Engineering News-Record*, Aug. 30, 1923, p. 357, to which the reader is referred for details not here repeated. The type of failure is unusual and its exact cause is somewhat puzzling. It is evident that more than ordinary care was exercised to obtain a good job, yet the dam failed suddenly and almost without warning with the water 10.5 ft. below the top, where it was being held by the discharge through the outlet tunnel.

The construction of the Apishapa dam is described in *Engineering News-Record* for June 16, 1921, p. 1030,

FIG. 8—HOLE IN DOWNSTREAM FACE OF APISHAPA DAM
Caused by leak through horizontal seams in sandstone of west canyon wall. The text indicates that this had nothing to do with the failure of the dam.

by Clair V. Mann, resident engineer. The dam is described as having been constructed to a height of 112.2 ft. A cross-section (reproduced in *Engineering News-Record*, Aug. 30, 1923, p. 357) shows that originally a height of 120 ft. was intended. Lack of funds prevented the completion to this height. The riprap was likewise carried up 60 ft. in elevation above the toe instead of to the top. The cross-section also indicates that the downstream one-fifth of the dam was made of coarse material. There remains at the east end of the dam an exposed cross-section about 45 ft. high and at the west end a section probably 60 ft. high, and there is no visible evidence that the material in the downstream fifth is any different from that in the other portions of the dam at the same elevation. From our observations at the site and information obtained from those familiar with the work it appears that in all other respects the dam was constructed substantially as shown on the cross-section mentioned.

Leaks—At different times in the past when the water in the basin reached within about 35 ft. of the top of the dam small leaks occurred through the rock underneath each end of the dam. Because of a recurrence

or these leaks and the rapid rate at which the basin was rising as a result of heavy rains at the Apishapa headwaters, A. N. Dallimore, chief engineer, and H. H. Knowlton, secretary-treasurer of the Apishapa Consolidated Irrigation Co., owners of the structure, were at the dam for some time before the failure with a force of about 40 men and some teams. Messrs. Dallimore and Knowlton are both graduate engineers and have been connected with the project since construction started—Mr. Dallimore in charge of the outlet structures and concrete and Mr. Knowlton in his present capacity. We are indebted to these men as eye-witnesses for a description of the failure and for information concerning the construction of the dam.

The small leaks had all been stopped or reduced to a harmless flow when the big leak that destroyed the dam started. There seems to be no question but that an open crack had formed diagonally through the dam from the upstream slope at the east end to the downstream slope near the west end. It hardly seems possible that such a crack could have been formed unless a large portion of one of the toes had settled or moved.

Composition of Original Material—The bottom 60 ft. of the dam was built of sandy adobe material taken from the river valley while the top 50 ft. was built of a light brown finely powdered material containing sand and gravel from high ground east of the dam.

There were probably 5,000 or 6,000 cu.yd. of the lower material left in the upstream portion of the dam at the east end, but practically none was left in the downstream portion, although a number of large masses of it had been washed down the valley [i. e., en masse (?) EDITOR]. Wherever this material was found it appeared to be damp throughout and resembled very much the outer edges of the core of a hydraulic-fill dam when exposed by a washout from the core pool.

Extent of Saturation—The light brown material in the upper part of the dam was very dry, so dry that whenever a small portion of it would scale off the nearly vertical exposed face and slide down to the river below a noticeable cloud of dust would rise. Each rolled layer was plainly visible. The top 2 or 3 in. of each layer was very hard, somewhat resembling soft shale. The rest of the layer, while fairly compact, could readily be dug out with a stick. At one place a quantity of this material had caved and fallen on a dry ledge of rock. It resembled road dust except for the small amount of gravel and slabs of the hard layers. In walking over this dry material, pulverized by the fall, one's feet would sink into it 6 to 8 in. This material apparently gave a very impervious fill. On the upstream slope of each exposed cross-section the line to which the water had penetrated could be followed for a distance down of 20 to 25 ft. in elevation from the water surface. At the lower depth the water had gone into the fill only 5 or 6 ft. Aside from some wet spots where leaks occurred from seams in the canyon walls this upper part of the dam appeared to have remained remarkably dry.

It seems likely that the material in the bottom 60 ft. of the dam became saturated or at least damp throughout and settled more or less, causing a slight movement in the downstream toe.

Cracks and Settlement—We were told that about a year ago a crack developed in the upstream face near the top of the west end and extended for some distance diagonally across the crest toward the east downstream slope. This crack was above the water in the basin at

the time. It was filled and puddled and gave no further trouble. It may be noted that this crack was symmetrically located, but crosswise to the crack that resulted in the failure.

The nature of the material in the top 50 ft. of the dam is such that cracks would be expected to develop in case of any appreciable uneven settlement. There may have been some tendency for this hard dry material to arch the 300-ft. rock canyon and crack, for certainly the rock shoulders of each bluff would prevent it from readily adjusting itself to settlement of the material below. The material in the bottom 60-ft. portion was quite probably somewhat susceptible to saturation and consequent settlement and spreading. The water could all have entered it through the upper slope, but on account of the drainage system in the downstream slope and the high tailwater in the valley below, resulting from the heavy outlet discharge, some water may have entered directly into the downstream portion.

Underdrainage—The drainage system for the lower toe is shown in the cross-section already mentioned. We were told that these drains had shown some flow of clear water after the basin began to fill and that this flow increased slightly with the increased head. Before the failure, for several hours, these drains had been covered with backwater from the outlet tunnel, but before they were covered the discharge was clear and was estimated to be about 1 sec.-ft. There was nothing to indicate that the flow underneath the dam contributed in any way to the failure.

Leakage Through Seams in Canyon Walls Not Cause of Failure—The dam contained a dangerous element of weakness. It caused trouble to develop, but this damage was repaired. It is fairly certain that the failure was independent of this weakness, although the symptoms were such as might lead to a failure. Water reached the portion of the fill downstream from the concrete cutoff wall through horizontal seams in the sandstone formation of the canyon walls. This was clearly seen in the saturated appearance of large spots in the face of the fill that remained at the west end of the dam. These spots were at the same elevation as the visible seams in the rock. Small leaks in the fill, no doubt from this cause, had been plugged and considered safely repaired prior to the failure. This was observed at both ends of the dam, in the portions remaining that were not affected by the failure.

Effect on Steel Cutoff Wall—The narrow canyon just below the dam was filled to a depth of about 25 ft. with material from the dam. This filling tapered out until it was hardly noticeable at a point 1,200 to 1,500 ft. below the dam. A small rim of the upstream toe covered with the riprap at an elevation of 25 to 30 ft. above the original creek bed was not washed out and its straight lines show that it had not moved. It is likely that the scour in the base of the dam reached bedrock during the heavy discharge and that this hole had been filled with material carried by the later smaller flow.

A steel sheet piling cutoff about 300 ft. long joined the concrete cutoff walls at each bluff. The piles were reported to be from 25 to 33 ft. long and their tops were at about the elevation of the old river bed. A thousand feet or so below the dam we found a portion of these piles. Although they were badly bent and twisted they were hanging together. Thirty piles were exposed but others probably were under the earth that

had been washed downstream. Those we saw were Carnegie sheet piling, 38 lb. per ft. It is possible that the entire steel cutoff was torn out. The concrete cutoff walls remain intact.

It was interesting to see the amount of silt that had been deposited in the basin above the dam. Although the dam was only finished in September, 1920, the old creek channel was entirely silted up and on the valley floor there was a deposit from 6 to 8 ft. deep.

Gage Height and Flood Down the Valley—The fight to save the dam was abandoned at 3:00 p.m. The gage was read at 3:45 and at each 15-minute interval until 4:45 when the water in the basin was below the gage. The accompanying table shows the readings and the discharges which they represent.

Time P.M.	Gage, Ft.	Total Fall, Ft.	Storage, Aero.-Ft.	Discharge, Aero.-Ft.	Average Rate of Discharge, Sec.-Ft.
3:00	82.9		18,500		
3:45	81.0	1.9	17,400	1,100	18,000
4:00	79.8	3.1	16,000	1,400	68,000
4:15	79.0	12.9	11,700	4,300	208,000
4:30	55.0	27.9	6,700	5,000	242,000
4:35	51.0	31.9	5,600	1,100	160,000
4:45	42.0*	40.9	3,600	2,000	145,000

* Bottom of gage.

The basin was seven miles long and rather narrow so that the slope of the water surface must have been considerable during the last few readings. This would indicate an exaggerated drop in gage and storage and consequently the later rates of discharge would be somewhat too high.

The flood water reached a point down the valley eleven miles below the dam at 5:20 p.m., according to one man and 5:30 according to another one near by. At this time there was quite a large flow still passing the dam site and the total length of the moving body of water must have been fifteen to eighteen miles. As the deepest water was near the lower end it would tend to get longer rather than shorter. This, together with the valley shortage, seems to account for the small depth of the flood wave and its low rate of travel. However, in determining the rate of the flood wave it would probably be more accurate to count from 4 rather than from 3 o'clock as the flow prior to 4 o'clock was comparatively small. This seems to be borne out by the fact that the flood wave reached the railroad bridge at the mouth of the river near Fowler 35 miles below the dam at 8 o'clock or traveled the last 24 miles in 2½ hours or at the rate of about ten miles per hour.

At this railroad bridge the valley is more than a mile wide while the bridge opening is probably not over 350 ft. long. The railroad embankment across the valley is from 10 to 15 ft. high and it formed a retarding basin which reduced the maximum flow that entered the Arkansas to 50,000 sec.-ft. or less. The flood wave down the Arkansas River was slow and more or less harmless. It reached Las Animas about fifty miles below the mouth of the Apishapa River at 11 o'clock the next morning and produced a rise of only 5 or 6 ft., while the maximum rise there occurred about two hours later.

Drainage Downstream—No loss of life was reported. One set of farm buildings was flooded 8 to 10 ft. deep and damaged considerably but not destroyed. These buildings were 11 miles below the dam and the farmer had been warned in time to get his family out about twenty minutes before the water arrived.

The two diversion dams of the project were not seriously damaged but the canal banks were overtopped

and broken at a few places. A few highway bridge approaches were washed out. The flood washed around the diverting dam of the Ft. Lyon canal about three miles west of La Junta and around the headgate of the Holbrook canal on the north side of the Arkansas, eight miles west of Rocky Ford.

Conclusion—It is apparent that this failure was not the result of carelessness or slighted work. It was not related to outlet or spillway structures inasmuch as these were separated from the dam and were not affected. We suspect that more water could have been used to advantage in rolling the material that came from the high ground, although we found no reason to consider this defect as a factor in the failure.

Our principal criticism of the dam as a whole is that the narrow rock canyon is not a desirable site for an earth dam. This criticism might be modified in case of a hydraulic-fill dam on account of its almost total freedom from settlement, but even then there would remain the uncertainty of maintaining a water-tight joint between the earth fill and the rock walls.

The failure was in the body of the dam, through a diagonal crack believed to be the result of unequal settlement brought about by subsidence and movement in the bottom portion of the dam. Eye-witnesses say they saw the water flow longitudinally through the dam in the diagonal crack and that neither extremity reached an abutment. This fact would eliminate theories that the failure originated from trouble at either canyon wall.

Engine Terminal Design, Capacity and Equipment

Track Layout and Enginehouse Leads—Rectangular and Circular Enginehouses—Turntable Capacity—Coaling Plants

Abstract of report of Committee on Design of Shops and Engine Terminals, presented at the annual meeting of the Mechanical Section of the American Railway Association.

Terminal Design—Engine terminals must be laid out so that one operation will not interfere with another. This requirement cannot be overemphasized. Few operations can be conducted efficiently for any length of time if the facilities are strained to the limit. To this end each facility should be designed to perform double the work ordinarily required and at important terminals duplicate facilities should be provided.

A single-track lead to an enginehouse is inexcusable. With three or more tracks available a majority should be assigned to incoming engines. Sufficient leads, switches and crossovers must be provided to avoid delays at coaling station, ash pit, inspection pit or other facility. As a general rule a number of short leads are preferable to a single long lead, as the former arrangement enables one engine to move independently of others. Where the number of leads is restricted, frequent crossover switches should be provided to prevent blocking any locomotive. The lead track to turntable should line up with corresponding tracks in enginehouse for convenience in placing dead engines.

Enginehouse Design—Modern enginehouses are divided into three classes: (1) brick wall with wood frame and roof; (2) reinforced-concrete frame and roof; (3) a combination of steel frame and reinforced concrete. The first is cheapest and most generally used, but the trend has been toward reinforced concrete. Enginehouses should be of fireproof construction as far as possible. Provision should be made for doubling the capacity needed, but it is first necessary to determine the class and extent of repairs to be made.

It is desirable to locate the house some distance from a city in order to get cheaper land, but it must not be too far away from an adequate labor market. The number of stalls to be provided is a function of the engines to be handled and the expected detention. If 100 engines are to be cared for and each may occupy a pit twelve hours, then fifty pits will be needed. If the average detention is only eight hours a day then thirty-four stalls will be ample. Quality of water (as affecting boilers) and amount of local switching may also exert considerable influence upon the number of stalls necessary.

Enginehouses are made in various cross-sections to suit local conditions, facilities, funds and tastes. Columns may be omitted in the drop pit section and trusses substituted. This provides a clear passage for moving wheels from the pits to the rear of the house. The outer row of columns should be made strong enough to support jib cranes, which may then be installed at any time desired. The modern house for a large terminal may have an overhead crane, down-draft ventilation system, boiler-washing plant, drop pits for driving, engine truck and tender wheels, jib cranes at frequent intervals and many other facilities. Practically all of the later enginehouses have increased head room to improve ventilation and lighting. The continuous monitor type of house, single or double, is now being more generally adopted. On several large roads the depth of the house has increased to 132 ft. The rear wall or outer circle wall should be practically all windows, with window sills about 4 ft. from the floor.

A rectangular enginehouse may fit the shape of the property better than a roundhouse. For large stations a transfer table may be located between two transverse rectangular enginehouses and some rectangular layouts will require both a transfer table and a turntable. In a rectangular house a transverse track arrangement is preferable to a longitudinal arrangement. The rectangular house, owing to its parallel spacing of pits, is easier and cheaper to build than a roundhouse. One particular advantage of the rectangular house with a wye track is the saving in space permitted inside the building on account of the parallel track arrangement. Leads and wye tracks cost less to maintain than turntables.

Turntables—Turntables are generally 100 to 110 ft. long, and 120-ft. length is being used for large engines. All turntables should be equipped with suitable tractor or tractors. One turntable is ordinarily sufficient for a 50-stall enginehouse. Such a house would provide for despatching 100 engines per day if each engine was detained in the house an average of twelve hours a day. This would mean 200 moves of the table daily, if each despatchment required two moves, one in and one out, and if all engines were despatched. In other words, the table must turn once every 7.2 minutes. If a peak load period occurs in which 25 per cent of the movements are made in four hours, this would require the table to turn once in every 4.8 min., which is about as fast as dependable operation will justify. Another consideration is the delay on account of failure of power or table, which in some cases may justify more than one table for an engine-house with less than fifty stalls.

The size of the turntable has a considerable bearing upon the number of stalls in the house, and longer tables permit more track approaches without having frogs in the track at edge of table. Generally, the longer the table the less waste floor space at outer circle of house, owing to reducing the angle of stalls. The turntable should be long enough to balance the engine when tender is empty. A deck turntable is preferable to a through type with shallow pit, when the cost of construction is not greater and when drainage will permit.

Coaling Stations—The type selected usually depends upon the number of engines handled, the number of tracks available for coaling engines and the kind of coal used. Station capacity should be at least a 24-hour supply and better 48-hour for maximum demand. The coal storage bins should be made self-cleaning as far as possible by proper sloping of floors. Gravity tipple outlet fixtures may be of the under-cut or over-cut type, but the over-cut fixture seems to provide more even mixing of coal delivered.

Mechanical coaling stations should be of the transverse type and a station serving several tracks is preferable to the longitudinal type because it facilitates engine movement to and from the station. When it is necessary to deliver coal to two or more tracks it is best to install a mechanical type of station. Loaded coal car tracks should have a down grade toward the track hopper to permit easy feeding of cars. The receiving hopper must be long and wide enough to handle a complete car and provide sufficient room for unloading and handling coal. The hopper should be protected from the weather. It is not good practice to have a steel coal chute too close to the ash pits, on account of fumes from wet ashes corroding the steel. A good many modern mechanical stations are built of concrete and have bucket conveyors. Under certain conditions a belt conveyor has been found satisfactory and economical. A coal measuring or weighing device is recommended for all coaling stations.

A longitudinal coaling station designed recently has the coal dumped into a pit below the ground level and a traveling crane with grab bucket lifts the coal to gravity chutes which deliver direct to tenders. This type of coaling station has a number of new features which may prove superior to other types in operation or economy.

Movement of B. Coli in Ground-Water and Pollution of Wells

Abstract of part of the 1922-23 annual report of the Board on Excreta Disposal, presented to the Conference of State Health Officers May 17, 1923, by C. W. Stiles, Professor of Zoology, Hygienic Laboratory, and Harry R. Crohurst, Sanitary Engineer, U. S. Public Health Service; slightly condensed here from the Public Health Reports, June 15, 1923.

IN CONNECTION with investigations by the United States Public Health Service into methods of disposal of privy wastes in rural districts, extensive and rigorously controlled experiments have been made which bear upon the movement of fecal bacteria in the ground-water. These studies have involved the experimental pollution of the ground-water (namely, the water in the saturated zone, which supplies wells and springs) and have been correlated with the rise and fall of the ground-water table, the flow of ground-water, and the rainfall. Natural can material (human excreta from can-type privies) was used as pollution material. *B. coli* was taken as the bacterial test, and a dye (uranin) was utilized in tracing the movement of the water from the dosing trenches to the more than 400 experimental pipe wells which were arranged at intervals from the trenches and at various depths into ground-water.

The examination of thousands of water samples from the wells during a period of more than a year has resulted in the following data regarding the movement of bacteria in sand:

1. Pollution with fecal *B. coli* has up to date been definitely and progressively followed in the ground-water for distances of 3, 6, 10, 15, 25, 35, 45, 50, 55, 60, and 65 ft. from the trench in which the pollution was placed; uranin has been recovered from these same wells and has spread to other wells at 70, 75, 80, 85, 90, 95, 100, 110, and 115 ft. from the pollution trench. The soil in question is a fine sand with an effective size of 0.13 millimeters.

2. The pollution has traveled these distances within a period of 187 days, or about 27 weeks, and only in the direction of the flow of the ground-water; no convincing evidence is present that the pollution has traveled against the flow of the ground-water or at right angles to it.

3. The pollution has traveled only in a thin sheet at the surface of the zone of saturation; there is no evidence at present that it has dispersed radially downward, and even when heavy pollution is recovered at the top, water from lower levels (in near-by deeper wells) is negative both for uranin and for *B. coli*.

4. As the ground-water level falls, owing to dry weather, the pollution tends to remain in the sand above the new (lower) ground-water level, namely, in the new capillary fringe.

5. There is no evidence which would justify a conclusion at present that either the bacteria or the uranin is carried or moves to any appreciable distance in the capillary fringe itself, and there is neither theoretical reason nor experimental evidence to justify a conclusion that either the bacteria or the uranin progresses in the dry, aerated intermediate belt (between the capillary fringe and the upper soil belt). All present evidence is to the effect that when the ground-water level falls the pollution remains practically stranded in the capillary fringe or in the intermediate belt—according to the degree of fall of the ground-water.

6. A rainfall of 1 in. results in a rise of 5 to 6 in. in the ground-water table (in the particular experimental area in question); and if this rise is sufficient to re-establish the zone of saturation up at the level of the stranded pollution, the bacteria and the uranin are again picked up and carried along farther in the direction of the ground-water flow until dry weather again intervenes to cause another fall of the ground-water level.

7. Thus the progressive (passive) movement and the stasis (stranding) of the pollution are intimately connected with, are dependent upon, and alternate with the rise and the fall of the ground-water level, and this latter factor is dependent upon the alternation of wet weather (rainfall) and dry weather (lack of rain at the intake area of the ground-water table). Experiments are now under way to determine, if possible, whether pollution placed directly into a deeper level of the ground-water will travel up to the surface of the saturated zone.

8. In explaining these results, capillarity, filtration, and gravity seem to come up for special consideration.

9. In one experiment the pollution traveled only 45 ft. from September, 1922, to May, 1923, and remained stranded at this distance. Study of the formation of the ground revealed that under the belt of pollution there is an impervious or nearly impervious stratum of peatlike material, which gradually tilts upward distally from the pollution pit and forms a ground-water dam; the pollution traveled out on high ground-water to the dam, the ground-water level fell below the crest of the dam, and the pollution is now stranded, pending a rise of the ground-water table sufficient to produce a ground-water cascade which will carry the pollution over the crest of the dam.

10. The ultimate distance to which the pollution will be carried is dependent upon a number of complex and interlocking factors, namely, wet and dry weather, with resulting rise and fall of the ground-water; the length of each of these periods; the rate of the ground-water flow (depending upon the "head," which, in turn, is dependent upon the rainfall); and, obviously, also the factor of the viability of the organisms under conditions of moisture, pH, food supply, etc., *ad finem*.

11. In another series of experiments human feces were buried in pits, in a locality of high ground-water, and covered with sawdust. Of five samples taken three years and two months after burial all were both macroscopically and microscopically recognizable as feces, but the odor had become somewhat musty; three of these samples were positive and two were negative for *B. coli*; ova of *Ascaris lumbricoides* were recognizable in all five samples, but all 57 ova found were dead.

12. The bearing of the foregoing results upon the intermittent pollution of wells, the location of water supplies, and the location of camps in peace or in war will be evident to persons who are called upon for technical advice in these matters; the justification of the laws forbidding the use of abandoned wells for the disposal of excreta is self-evident; the possible effect of the custom (in some localities) of digging pits into ground-water (as advised by some persons) is obvious.

13. In protecting wells, special attention should be given not only to surface protection, as is now generally recognized, but also to a new element, namely, the danger zone which exists from the highest water level to about a foot below the lowest water level. A leak in the pipe in this region is potentially very dangerous, and all wells unprotected in this danger zone are to be considered as potentially unsafe.

Deferrizing Additional Water Supply of Berlin

Aeration Followed by Rapid Passage Through Gravel Beds and Sand Filters Removes High Iron Content of Ground Water of Additional Supply for German Capital

BY GORDON M. FAIR

Instructor in Sanitary Engineering, Harvard University,
Cambridge, Mass.

DEFERRIZATION is one of the most important problems of water supply in the glaciated areas of middle Europe. German engineers have solved it in a variety of ways, among which the methods used for the purification of the additional water supply of Berlin present numerous departures from common European practice. The extension of the water-supply system of the German capital was completed just prior to the outbreak of the Great War. As a result, it is little known and has since completion not even been de-

The new plant is situated about seven miles east of Berlin in a forested area about three square miles in extent, known as the "Wuhlheide." The region is traversed by the sandy bed of an ancient glacial stream whose modern progeny is the much smaller river Spree. The bank of the ancient river bed, rising 150 ft. above the plane, forms the catchment area of the ground water flowing towards the Spree. The water is intercepted by means of 154 wells that parallel the river and yield from 6 to 17 m.g.d. The highest demand is made upon the plant during the four summer months, when it delivers 17.2 m.g.d. to the city; the lowest demand occurs during the three winter months, when the pumpage sinks to 5.7 m.g.d. During the five spring and fall months, 11.5 m.g.d. of water are used. The water contains relatively large amounts of iron which is removed by aeration and double filtration. The pumping station and purification works are situated in the center of the well field. A general plan of the plant is shown by Fig. 1.

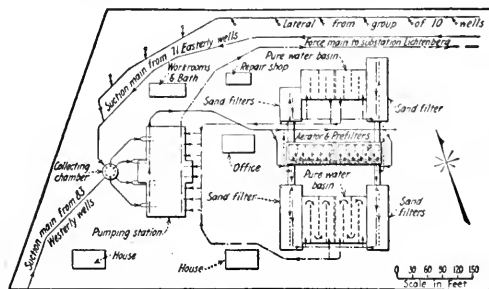

FIG. 1.—GENERAL PLAN OF PUMPING STATION AND DEFERRIZING PLANT OF BERLIN WATER-WORKS

scribed in the German technical journals. The present description of the plant is based upon observations made by the writer when he visited the works, supplemented by information just received from one of the plant engineers, who furnished the writer with the illustrations.

Sources of supply—The central city of Berlin, with a population of about 1,500,000, obtains its water supply from three sources, all of which require treatment for iron removal. The oldest collecting and purification works still in operation were built in 1877. This plant, situated on Lake Tegel about seven miles from the heart of Berlin, has a capacity of 17.5 to 23 m.g.d., the maximum demand occurring during the summer months. The supply is obtained from wells driven along the lake shore. The iron bearing water (1.2 to 3.4 mg. Fe per liter) is aerated prior to slow sand filtration. In 1893 a second plant, with a capacity of 64 m.g.d., was put into operation on Lake Müggel about eleven miles from the city. It derives its supply from three different sources. The bulk of the water is obtained from driven wells intercepting the underflow towards the lake. This water, containing 1.1 to 2.9 mg. Fe per liter, is purified by aeration and slow sand filtration. From 10 to 20 per cent of the supply is drawn from Lake Müggel itself and purified by slow sand filtration alone. About 5 m.g.d. are pumped from the lake on to large sandy areas whence the water percolates into the ground to increase the well water. In 1910 the rapid growth of Berlin necessitated the construction of a third plant, which was completed in July, 1914.

The Wells—The wells are driven at intervals of 80 to 160 ft. to a depth varying usually from 115 to 200 ft. The extreme westerly wells, in the driving of which heavy strata of clay were encountered, penetrate to a depth of 325 ft. A main conduit receives the flow of 83 westerly, another that of 71 easterly wells. The average daily yield of each well is 78,000 gal., the demand varying from 38,000 to 111,000 gal. The wells are connected in groups of six to ten that discharge through a metered branch line into the collecting main. The branches and individual wells can be closed off separately. The wells are constructed of seamless drawn copper tubing provided at the proper depth with a strainer whose slots are protected by copper screening. The collecting conduits are laid on a slope of 1 in 4,000 and lead to a receiving chamber situated in front of the pumping station. The diameter of the mains increases gradually from 8 to 43 in. The drop leg of the main leading into the receiving well is reduced to 36 in. Two rotary air pumps remove the air from the suction mains to start the flow of water and operate automatically in removing the gases discharged by the water, thus preventing interruption of flow.

Collecting Chamber—The collecting chamber, 26 ft. in diameter and 13 ft. deep, is constructed of brick walls built upon a heavy reinforced-concrete foundation. A cross-wall bisects the structure. Each collector main discharges into one of the compartments thus formed. A suction pipe from a low-lift pump enters each half of the collecting chamber. The two compartments communicate by means of gate-controlled openings in the dividing wall. It is possible to operate either half of the plant independently of the other. Electric indicators in the superintendent's office and in the pumping station record the water level.

Pumping Station—The pumping station, about 80 ft. from the collecting chamber, like the remaining build-

FIG. 2—VIEW OF BERLIN WATER DEFERRIZATION PLANT, LOOKING EAST

ings of the plant, is a reinforced-concrete structure finished on the outside in yellow-brown stucco with a red tile roof. In the construction of its foundation and waterproof basement the ground water level had to be drawn down over 20 ft. The main pumping-equipment consists of four sets of electrically driven raw-water and pure-water pumps of the double-acting plunger type. During the winter only one set is in operation; during the spring and fall, two; during the summer, three. The fourth set remains in reserve. The raw-water pumps operate vertically. They are situated in the basement of the building. The horizontal pure-water pumps occupy the main floor of the station. Each pumping set consists of a raw-water and a pure-water pump attached to a common shaft operated by a synchronous alternating-current motor. The capacity of each raw-water pump at 70 r.p.m. of the motor is about 6 m.g.d. The pure-water sister pump has a capacity smaller by 8 per cent to allow for wash water losses and other plant uses. When less than 8 per cent of the water is actually consumed, the excess is permitted to accumulate in the pure-water basins and is pumped from time to time to the city by means of two special centrifugal pumps. The raw-water pumps force the water through a common main to the aerators. The pure-water pumps take the treated water from the clear-water basins and force it through a 36-in. main to large storage basins in the substation "Lichtenberg" on the outskirts of Berlin, whence it is pumped under the requisite pressure into the distributing system of the city. Each pump is equipped with a suction and discharge air chamber. The main conduits are further provided with special air chambers 6½ ft. in diameter and 26 ft. high. Strong check valves are inserted in the 5.6-mi. force main to Lichtenberg to prevent flooding of the pumping station in case of a break of a main within the building.

Aerators—Two aerating chambers are situated in the upper story of the pre-filter house (Fig. 2). The raw-water main runs the whole length of the build-

ing and branches into horizontal aerator feed pipes controlled by separate gates. Each feed pipe supplies 40 nozzles screwed into the pipe at 3-ft. intervals. The aerator nozzles (Fig. 3) are of the double-jet type. They have a capacity of 32 g.p.m. (46,000 gal. a day) and divide the water into a fine spray that falls within a radius of 8 ft. Fig. 4 shows one of the nozzles operating as a lawn sprinkler. Ventilators provide circulation of air through the falling water. The ferrous iron dissolved in the water is oxidized rapidly and precipitates. Hydrogen sulphide and carbon dioxide present in the water are removed at the same time.

Gravel Filters—The drops of the water from the aerator are caught upon ten prefilters or scrubbers situated beneath the aerating chambers (Fig. 5). The area of each bed is 442 sq.ft. (about 1/100 acre). The filtering medium is 24 in. deep and consists of gravel 6 to 10 mm. in diameter resting upon a false bottom of perforated copper plates. The gravel is arranged in two layers placed between copper screens to prevent its displacement during washing. The average rate of filtration is 168 m.g.d. per acre, with a filter period approximating 100 hours. When the gravel has become clogged with iron, the filter is washed by reversing the flow and introducing compressed air beneath the filter. The air is obtained from two five-step turbine blowers each capable of delivering 1,750 cu.ft. of air per minute against a head of 10 ft. of water. Distribution of the air under the filter is accomplished by means of a system of 2-in. pipes provided with ½-in. orifices. The coarse pre-filters remove about 50 per cent of the precipitated iron. The filtered water passes by way of an overflow to the sand filters situated in four buildings connected to the aerator house by covered passageways. The wash-water is conducted to two 26x130-ft. sedimentation basins, in which most of the iron sludge settles readily. The clear effluent from these basins flows through a ditch to the River Spree.

Sand Filters—There are sixty filters (Fig. 6), of the rapid sand pressure type, called "Bollmann" filters after their designer. Three of the filter buildings contain eighteen tanks each; the fourth has but six. The filters operate under a head of 10½ to 11½ ft. of water and each delivers on an average 317,000 gal. a day. The filtering surface is 67 sq.ft., the average rate of filtration therefore being 206 m.g.d. per acre. The initial rate approaches 240 m.g.d. The diameter of the filtering quartz sand is 0.8 to 1.5 mm.

Each filter tank (Figs. 7 and 8) consists of a steel shell 9 ft. in diameter and 8 ft. high, with a 4-ft. conical bottom, resting on cast-iron columns. The shell is closed water-tight with an arched cover. An air valve situated on the cover operates automatically when the filter is filled or emptied. The water enters at the top of the filter and flows over a distributing gutter on to the sand, passing through it to the underdrains. These are situated 5 ft. below the sand surface and

FIG. 3—AERATOR NOZZLE

FIG. 4—AERATOR NOZZLE IN OPERATION

A conical spray ascending at an angle of 60 deg. is obtained.

consist of 2-in. bronze laterals branching from a cast-iron main. The laterals are provided with fine slits $\frac{1}{2}$ in. wide and 8 in. long cut into three-quarters of the circumference of the pipe, the unperforated quarter facing upward. The effluent pipe is arranged in the form of a gooseneck vented at the top to prevent siphonage. After a filtering period of 100 to 120 hours

of the filter, about 160 cu.yd., is washed in 1 to 12 hours. The process requires but slight supervision. The double conical body in the bottom of the filter conducts the sand to the injector in uniform quantities. The wash-water required does not exceed 2.2 to 2.5 per cent of the water filtered.

Some of the filters were opened in the writer's presence after being in service for $5\frac{1}{2}$ years or longer. The sand was removed mechanically by means of the injector and sifted. The sand loss during the long period of operation, together with the sand discarded as having become too fine, amounted to 0.1 per cent of the filter contents. The sand was free from incrustation as was the shell itself. The bronze under-drains were slightly corroded and some of them had to be replaced.

Pure-Water Basins—The four pure-water basins (Fig. 6) have a combined capacity of 1.6 m.g. They are constructed of brick walls upon a watertight concrete floor. Each basin has three round-the-end baffles that prevent stagnation of the water. They are roofed over and covered with 40 in. of sodded earth. A water tower (Fig. 9), holding 80,000 gal., serves the suburb "Oberschöneweide."

Results of Operation—The raw-water delivered to the plant is colorless and, due to its high iron content,

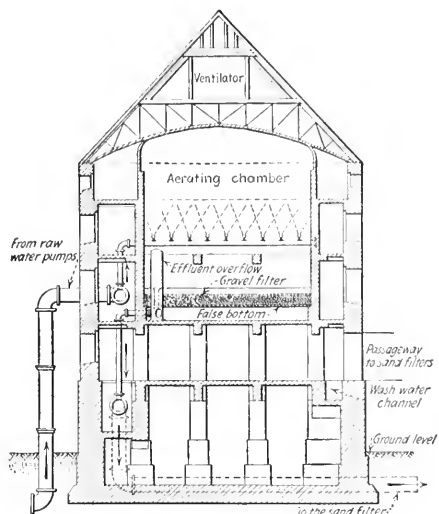

FIG. 5—AERATOR HOUSE AND GRAVEL PREFILTERS

FIG. 6—RAPID SAND FILTERS AND PURE-WATER BASINS
The filters operate under a head of 11 ft.

the rate of filtration has commonly decreased to 144 m.g.d. per acre, when the filter is washed by reversing the flow for eight to ten minutes. This method of backwashing is effective for six to eight times, that is, for three to six weeks. A thorough cleansing of the sand grains then becomes necessary. This is accomplished by means of an injector situated at the bottom of the conical filter bottom. When the injector is operated the sand is sucked into the injector discharge and thoroughly scoured in its upward passage through a vertical tube situated in the center of the filter and rising above the sand surface. The washed sand (spec. gr. 2.65) falls on to the sand bed, the waste water carrying with it the lighter iron deposits (spec. gr. 1.18) flows over a peripheral wash-water gutter to the wash-water sedimentation basins used in connection with the prefilters. The sand content

FIG. 7—CROSS-SECTION OF BOLLMANN FILTER

The sand is washed by reversing the flow of water through the underdrains. When this is no longer effective the injector at the bottom of the filter is used.

becomes opalescent on standing. It has a slight odor of hydrogen sulphide, is rather hard, but bacteriologically very pure. During five years of operation the iron content has increased from 4 to 8 mg. per liter, together with the other mineral substances. The sanitary quality of the water has remained unchanged. Aeration and filtration remove the iron and manganese

FIG. 8—ARCHITECTURAL TREATMENT OF WATER TOWER OF BERLIN DEFERRIZATION PLANT

almost completely and the pure water is colorless, remains clear on standing, and is odorless. Results of analyses in March, 1915, and August, 1921 (latest available) are shown in the accompanying table. There is no routine laboratory control of the purification

Final Report on Franklin Furnace Typhoid Outbreak

The cross-connection water-borne typhoid outbreak at Franklin Furnace, N. J., late in 1922 (see *Engineering News-Record*, Dec. 7, 14 and 28, pp. 959, 1045 and 1134) caused 114 known cases and 18 deaths, according to the final report on the subject recently completed by Cecil K. Blanchard, assistant epidemiologist, Bureau of Local Health Administration, New Jersey State Department of Health.

An open gate valve and a leaky check valve, both apparently forgotten, between the industrial and the town water supply systems of the New Jersey Zinc Co. were established by tests conducted jointly by the state health authorities and the company as the probable cause of the epidemic. The probable specific infection was two cases of typhoid the dejecta from which would naturally reach the Walkill River a short distance above the intake of the industrial water-supply system.

Inoculation against typhoid was voluntarily taken by nearly half the population of the borough. This and hospitalization, etc., were provided at the expense of the Zinc Co. The local health authorities are credited with efficient work during the outbreak. The State Department of Health undertook, for the first time in connection with an epidemic, to secure two successive negative specimens of stool and urine from all typhoid convalescents before releasing them from jurisdiction—a procedure followed with dairy typhoid cases for some years and held to be "the only method now available to secure gradually a record of the typhoid carrier population." Illness of the local health inspector prevented the completion of this program. Only two known secondary cases among the total of 114 cases occurred.

D. C. Bowen is chief of the New Jersey Bureau of Local Health Administration.

Identification of Douglas Fir

Douglas fir is one of the largest, most abundant and most widely distributed species of trees native to North America, and, next to the southern yellow pines, it is cut in the greatest quantities of all woods of commercial importance. It belongs to the coniferous family and is, therefore, a softwood. Other names for Douglas fir are red fir, yellow fir, Oregon pine, Puget Sound pine, red pine, red spruce, and Douglas spruce. Its botanical name is *Pseudotsuga taxifolia*. As there is a considerable range in the price and suitability of various similar softwoods, the Forest Products Laboratory gives the following identification features: Douglas fir is a resinous wood, with a characteristic sweetish odor. Exudations of resin on end and side surfaces and pitch pockets are common. Occasionally pitch streaks occur. The sapwood, which is from 1 to 3 in. wide, is white. The freshly cut heartwood is light reddish yellow in color. On exposure to light and air it becomes distinctly reddish, sometimes cherry red, or reddish brown, except the outer portion of old trees which often remains light reddish yellow, which explains why the wood is sometimes known as yellow fir. The summerwood is pronounced, except in very narrow rings such as usually occur in the outer portion of old trees. Under the microscope Douglas fir can easily be distinguished from other structural softwoods by the fine spiral thickenings on the inner side of the cell walls, similar to the thread in a nut.

process, and the hygienic quality of the water is considered sufficiently constant and secure to require examination of the water from that viewpoint at rare intervals only.

Concrete Bottom for Mechanical Water Filters

Metal Strainer and Air-Wash Replaced by Concrete Channels, Half Cylinders and Spheres Giving High Velocity Wash

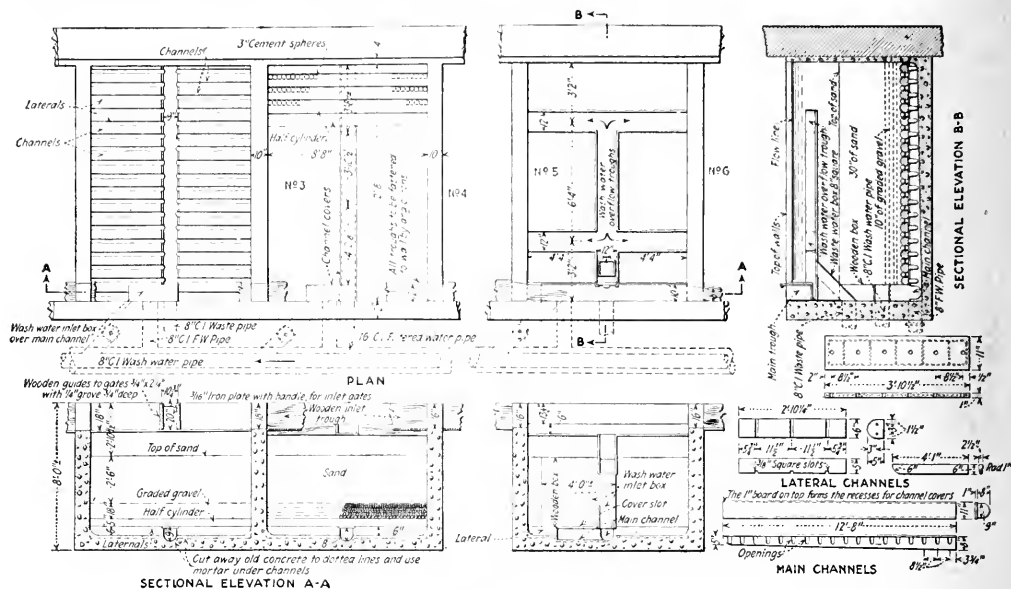

By A. L. GAMMAGE
Engineers' Club, Boston, Mass.

AN ALL-CONCRETE bottom for mechanical water filters has been developed which can be built with a strainer system having any desired ratio of slot discharge to filter area. It can have any proper ratio of length to diameter of laterals. It has side jets which effectively break up and distribute the wash water so there is no danger of lifting movable elements of the filter gravel. Each of a series of upper channels is fed

of the stream varies from a little more than the 3 to 4 m.g.d. of water used in the mill processes to over 20 m.g.d. at flood time.

The water is highly colored, polluted with suspended organic matter, and low in alkalinity. The color varies from 60 to 200 on the platinum scale; the suspended matter from 10 to 25 p.p.m., with about two-thirds organic, and the alkalinity from 3 to 16 p.p.m. The hydrogen-ion pH is almost always 6.0 or less. The filtered water has a color of 10 to 20 and may be easily made 5 or less.

Nine 4-m.g.d. air-wash mechanical filters were formerly used to filter the alum-treated water. The strainers and galvanized-iron laterals of these filters corroded so rapidly that they were continually being replaced at considerable expense of money and loss of time in filter operation. The air-wash filters were unequal to the load

Bottom wholly of concrete, including channels, raised half-cylinders with horizontal under-slots to form jets and with

spheres placed in the spaces between the tops of the half cylinders.

by two separate lower channels. This gives a uniform flow of wash water which the upper channels distribute evenly over the filter floor. There are no pockets below the jets, as in the perforated-pipe system. The all-concrete bottom will effectively break up and evenly distribute the highest velocity jets of water. This type of bottom has been developed in the period from 1919 to 1923 at the plant of the Hollingsworth & Vose Co., at East Walpole, Mass.

The company just named is the largest manufacturer of rope and jute manila papers in the world. Its East Walpole plant is located on the Neponset River. This stream heads in the Neponset reservoir, Foxboro, Mass. A short distance below its source it is joined by a brook carrying the effluent from the sewage-works of a state hospital. The river is also polluted by trade wastes from rubber factories, cotton washing, bleaching, and dyeing plants, and cotton and paper mills, before it reaches the Hollingsworth & Vose mill pond. The flow

of work, and about every six months all sand and gravel was removed and replaced by new material.

It was thought that an all-concrete filter would be non-corrosive and if the filter bottom had a large ratio of slot to filter area the velocity of wash water would be great enough to lift the sand and make a high-velocity wash filter. One of the old air-wash filters was changed into a filter built with spheres over lateral channels and a slotted filter bottom with total discharge openings equal to about 4 per cent of the filter-bed area.

This filter worked excellently while it was clean. Until the sand clogged the wash water lifted the whole bed and washed it well. When the sand became dirty the gravel shifted and sand and alum hydrate and suspended dirt passed the filter. The filter bottom was rebuilt several times with decreasing ratio of slot discharge to filter area until a filter bottom was built with raised half cylinders having $\frac{1}{2}$ -in. horizontal under-

slots 20 in. apart lengthwise, which covered the lateral channels and threw jets opposite each other to a top series of lateral channels covered by 3-in. spheres and gravel and sand. This filter unit had a ratio of slot discharge to filter area of approximately 0.3 to 100. It worked so well that filters 4 and 6 were changed likewise, so that we had filters 1, 4 and 6 on high-velocity working alongside the original 2, 3 and 5 air-wash filters.

The results on comparative tests were such that the company built three new Gammage filters after sketches dated Oct. 20 and Dec. 8, 1919 (not reproduced here). These filters had a ratio of slot discharge to filter area of 0.5 to 100. While this ratio is high, the filters have always filtered and washed evenly, leaving a level sand bed when the sand was dirty. Closing each alternate jet gives a ratio under 0.3 to 100, but this has not been done and no gravel upset has occurred.

To secure a sufficient flow of water from the coagulation basin to the new filters the supply line had to be enlarged to furnish sufficient water for all filters.

After the new filters had been run successfully for some time it was decided to change over three suction filters to high-velocity filters, as all others are gravity filters, and these are giving satisfactory results. They have a ratio of slot discharge to filter area of some 0.4 to 100.

About a year later it was decided to change over the three remaining gravity air-wash filters to high-velocity, and as all the filters were now washing under a 100-ft. head it was decided to tighten the filter bottom to a ratio 0.28 to 100, as shown in the accompanying sketch. On full head the wash water was 28 in. a minute upward in a filter without any sand or gravel in place.

There are three filters each with a ratio of slot area to filter area of 0.28, 0.3, 0.4 to 100 and one of 0.5 to 100 and all are working under a higher wash-water head than is usual in mechanical filters. This wash-water head was used at the East Walpole plant because a tower tank built to supply a certain pressure to the showers of the paper machines on the floor above the filters was the only available wash-water source.

A number of the concrete filters have been surface treated with a zinc magnesium fluosilicate, to form a hard wearing surface.

Acknowledgment is given to John Cashman for all the drafting work and great credit is due the Hollingsworth & Vose Co. for co-operation in the development of a new mechanical filter bottom which is giving them good satisfaction. This mechanical filter bottom has been patented by the writer and has been leased to most of the largest filter companies in the United States.

Crystalline Areas in Wrought-Iron Fractures

Crystalline areas in the nicked-bend fracture of a wrought-iron bar do not necessarily indicate the presence of steel in the material from which the bar was made, nor do they indicate high-phosphorus iron, the Bureau of Standards has found. On the other hand, the presence of steel in the material of the bar does favor the formation of such crystalline areas, because it tends to produce uniform distribution and small size of the individual slag threads, and this latter condition is closely connected with the development of the crystalline areas. In such a test the crystalline areas developed on the tension side of the tested bar are more significant than those on the compression side.

Disinfecting the City Water Mains of Otsego, Michigan

Hypo Applied at Pumps Until Reactions Positive at Flushed Dead Ends—Flushing Kept Up Until Reactions Negative

BY EDWARD D. RICH

Director, Bureau of Engineering, State Department of Health, Lansing, Mich.

TO DISINFECT the seven miles of city water mains after sewage-polluted and muddy water from the Kalamazoo River had been used for years was the problem confronting O. G. Bacon, city manager of Otsego, Mich., three months after a deep-well water supply had been put into use and the river intake disconnected. The work was done by dosing the pump well heavily with hypochlorite and flushing the hydrants until a reaction for excess chlorine was obtained by ortho-tolidin tests. Flushing was kept up after the hypochlorite was discontinued until negative tests were obtained. The work was supervised by the Engineering Bureau of the State Department of Health, with W. C. Brockway in charge.

DEEP-WELL PUMP HOUSE

Located on top of concrete pump well into which deep-well pumps discharge. The two deep wells are drilled through the bottom of the pump well.

Otsego had a population of 3,168 in 1920. While the river had been drawn upon for eight years it was not supposed to be used for drinking purposes. Sewage from Plainwell, population 2,000, four miles above Otsego by river, and from Kalamazoo, population 48,000, fifteen miles above, is discharged into the Kalamazoo River.

The consumption of water is estimated at 400,000 gal. per day. Ten dead ends, mostly on 4-in. mains, exist, ranging from 400 to 1,000 ft. in length. Circulation on many of them does not take place unless hydrants are flushed because there are scarcely any house connections.

It was necessary to clear the mains of mud to get the maximum efficiency from the hypochlorite. For this reason the dead ends were flushed first. Then, starting from the pumping station, hydrants were flushed in order depending upon their distance from the station. After the entire system had been flushed and practically all of the turbidity removed, the dead ends only were opened. The color of the water from some of the dead ends when first flushed was jet black, and as much as one hour was required in some instances before the water became clear in appearance.

After the hypochlorite solution had been applied to the water for 24 hours, dead ends were flushed until a positive reaction for excess chlorine was obtained. Water not chlorinated was not entirely discharged from the system until two days after treatment began. One workman was kept busy continuously at flushing hydrants from Sept. 18 to Sept. 25, 1922, when the hypochlorite dose was discontinued, and until the ortho-tolidin test for excess chlorine gave a negative reaction, which was several days later.

The 130,000-gal. pump well into which the deep-well

pumps discharge water with much agitation at one side of the well, and from which the high-lift pumps have an intake at the other side, offered a possibility for applying the hypochlorite without the offensive task of mixing it into solution manually. With this arrangement the erection of an emergency or temporary plant was not necessary. Accordingly, about 28 lb. of hypochlorite was put into a sack and suspended by means of a rope at the end of the deep-well pump discharge, where the agitation of the water was quite effective in dissolving the chemical. A large initial dose, equivalent to 9 p.p.m. for the 130,000 gal. in the well, was used so that the strength would not be unduly dissipated by this large volume.

Hypochlorite was placed in bags in preference to throwing it directly into the well, because the dose could be controlled better. If the treatment had to be discontinued at any time, the bags could be removed. If the chemical had been thrown into the well, it would

Treatment applied Sept. 19 to 25 but chlorine persisted until Oct. 2

have been necessary to wait until the chemical was dissolved. By placing it in bags, no lumps were drawn into the distribution system, thus making the dose more or less irregular and uncertain.

An improvised mask, used by the men at the paper mill where the hypochlorite was obtained, was employed by the city workmen, so that no ill effects from handling were evident.

It was found that 21 lb. placed in the well every two hours during the day for seven or eight doses, 15 p.p.m. for an average dose of 400,000 gal. daily, was satisfactory. Since the consumption of water (not for drinking) was low at night, a dose of the disinfectant was placed in the well at 9 p.m. and not replaced until 7 a.m. the next day. Bags previously placed were not removed when a new one was put in. One bag lasted many hours, so several bags were in the well at the same time. The detention period and storage capacity furnished by the pump well were relatively great. These factors and the fact that hypochlorite dissolves slowly, were particularly favorable for this scheme. By means of the ortho-tolidin test it was discovered that the chlorine traveled through the pump well in less than 20 minutes, as shown by the positive reaction in a sample collected from a pet cock on a high-lift pump.

The initial treatment was not deferred until the mains were all flushed, but was commenced at noon, Sept. 19, and continued until Sept. 25, because flushing would draw the treated water to the dead ends that much sooner, even though the presence of organic mat-

ter and mud would make the dose less effective. If the treatment had been deferred, a second round of flushing would have been required to replace the raw water with chlorinated water which would have delayed the work about two days.

The only way of testing the efficiency of the treatment was by means of bacteriological specimens sent to the laboratory of the State Department of Health at Lansing. Before, during and after treatment, samples were collected daily from the raw well water and from taps and dead ends on the distribution system. U. S. Treasury Department standards were used for classifying results. To be considered "safe" the "count" was required to be less than 100 with not more than one out of the five 10-c.c. plantings showing gas followed by positive confirmatory results. If the count were greater than 100, and more than one out of five 10-c.c. portions showed gas, the specimen was considered "safe" provided the confirmation was negative, but if the confirmatory test were positive under these conditions, the specimen was classified as "Suspicious" if the standard was but slightly violated, and "unsafe" if decidedly in violation.

Due to delay in shipping (from 24 to 48 hours elapsed before the specimens were planted) it is believed that the counts increased materially and the above classification in consequence is too severe. The result of this classification is that the specimens considered as "suspicious" should in fairness probably be classified as "safe." In most instances, these samples had a count exceeding 100. In some cases specimens classified as "suspicious" were not confirmed but they were so classified because the count of 100 was exceeded. After-growths in the dead ends and during the sample transportation period both tended to give less favorable results than the actual condition would justify.

Pitometer Survey Discloses Underground Leaks

DURING the course of a pitometer survey in Detroit to locate water waste many kinds of leaks were discovered. Photographs were often taken for permanent record of some of the more striking instances to indicate the nature of the defects. Six leaks all in the street are shown on p. 433.

The survey was started July 1, 1919, by the Pitometer Co., which submitted its final report March 1, 1922, since which time a pitometer division of the water department has continued the work. The Pitometer Co. located and the department repaired underground leaks amounting to 9,557,000 gal. daily. There was also 3,380,000 gal. daily of unmetered fixture leakage and 9,600,000 gal. daily of metered fixture leakage eliminated, representing a total of 24 gal. per capita per day saved. The per capita consumption for the year ending June 30, 1922, was 148 gal. Detroit supplies 954,500 people and has 98.5 per cent of the taps metered.

As a result of the survey a systematic removal for test of all house meters is now under way. More than \$200,000 is the estimated money saved annually.

The water-waste investigations were carried out under the general direction of George H. Fenkell, superintendent and general manager, Detroit Water Department. The department's pitometer survey is being carried out by Maurice N. Girardy, reporting to F. H. Stevenson, assistant superintendent.

Six of the Leaks Revealed by Pitometer Survey in Detroit's Water Supply

1. DEFECTIVE GASKETS ON STANDPIPE FOOT VALVE

2. BROKEN 6-IN. MAIN; LOSS, 281,000 G. P. D.

3. A 3-IN. LEAD BROKEN AT CORPORATION

4. SPLIT AND BREAK IN 3-IN. LEAD SERVICE

5. VIBRATION BLOWS JOINT ON THIS 4-IN. SLEEVE

6. BLOWN JOINT ON CROSS UNDER CATCHBASIN WALL

Japanese Engineering Structures and Services

Notes on Status of Development in Buildings and Water-Works Before the Earthquake
—A Background to Aid Interpretation of News Reports

As a background for later and more detailed reports regarding the effect of the earthquake which shook Japan, Sept. 1, the following notes on structures and services of engineering interest in Tokyo and Yokohama are presented. The comments on building design are based on an interview with Col. W. A. Starrett, of New York, who was connected with the construction of the first large steel office buildings erected in Japan.—EDITOR.

FROM THE fragmentary news that has reached this country regarding the appalling earthquake tragedy in Japan, Sept. 1, it is impossible, as yet, to form any reliable estimate of the effect of the shock on the principal engineering structures in the devastated areas of Tokyo and Yokohama, where, apparently, the most severe damage has occurred. With the loss of life reported as running into the hundreds of thousands the purely technical phases of the great disaster assume a position of secondary importance. Nevertheless, it is certain that in the wake of the world-wide effort that has been started to alleviate the human suffering caused by the great catastrophe, will come many valuable engineering lessons.

MARUNOUCHI BUILDING, MODERN STEEL STRUCTURE
Built by American constructors and reported standing.

The topography of Japan is mountainous. Tokyo, capital of the Empire, comprises uplands and lowlands, with hills ranging from 50 to 130 ft. high. It is located at the head of Tokyo Bay on the southeast coast and along the Sumida River. There are flats on both sides of the river intercepted frequently by canals, over which there are many small bridges. Tokyo is about 18 miles distant, by railway, from Yokohama, the seaport. According to the 1920 census, the population of Tokyo was 2,173,000 and of Yokohama 423,000. For years past records show that Japan is subjected, on the average, to three or four seismic disturbances daily.

Ancient and Modern Structures—While it is true that in design and construction many of Japan's buildings, bridges and other works of the engineer hark back centuries, the application of modern American and European building practice has long since been under way. Within comparatively close range stand the picturesque masonry palaces of the old Empire, the low, flimsy structures of wood or brick in the residence dis-

tricts, and modern skeleton steel-frame office buildings of the skyscraper type comparable with those that flank lower Broadway in New York. For the engineer, the earthquake, when the full story is known, will undoubtedly contribute valuable information on the comparative stability of the old and the new structures under conditions of extreme shock such as occurred last week. In addition to the modern steel buildings to which reference has just been made, a considerable amount of reinforced-concrete building construction has been in progress in the leading cities of Japan for a dozen years or more. Have these structures stood, and, if so, to what extent have they been damaged? How does their condition, after the earthquake, compare with that of the skeleton steel buildings? Are modern methods of engineering design capable of producing structures which can resist collapse under such conditions as were created by the earthquake in Japan? These are some of the questions to which engineers, the world over, will seek an answer. The data necessary for an analysis of the results are not yet available.

From present reports, however, the indications are that extensive damage has been done not only to buildings, including private residences and commercial structures, but also to the bridges, water-supply and gas systems of Tokyo and Yokohama. In fact, breakage of the water-supply mains is given as one of the chief reasons to account for the failure to check the fires which swept the stricken cities immediately after the earthquake. Later reports indicate that the water supply systems have been partially restored to service.

Modern Structures Stand—The one encouraging feature in the news thus far received is the probable safety of certain large steel frame office buildings constructed last year in Tokyo by an American organization, the George A. Fuller Co. of New York. These buildings, described in *Engineering News-Record*, Sept. 21, 1922, p. 476, are all about 100 ft. high (eight stories) and in their design great stress was laid upon providing resistance to earthquake shock in the form of heavy sway-bracing and the provision of adequate foundations by driving timber piles to a firm support 40 to 60 ft. below the surface. The largest of these structures, known as the Marunouchi building, in Tokyo, was eight stories high and covered a plot 340x300 ft. The other two structures were of the same skeleton steel frame type, although somewhat smaller in volume, and were built for the Nippon Yusen Kaisha Steamship Line and for the Japan Oil Co. Through the New York office of The Mitsubishi Co., the big Japanese banking and exporting organization, reports have been received which lead the American constructors to believe that all three structures are standing, although no details are available as to the extent of the damage done to them by the earthquake. These buildings represent the first use, in Japan, of American steel frame office building design and construction. Up to the time they were begun in 1920, modern construction in Japan found its expression chiefly in reinforced concrete.

One of the leading examples of a large reinforced-concrete building in Tokyo is the new Imperial Hotel,

shown in one of the accompanying illustrations. It is faced with brick and is a long, low structure. Reports state that it withstood the shock of the earthquake.

COLONEL STARRETT DISCUSSES BUILDINGS

In connection with the design and erection of these steel buildings Col. W. A. Starrett, formerly an officer of the George A. Fuller Co. and now member of the firm of Starrett Bros., Inc., New York, has made three trips to Japan since 1919. In an interview last week with *Engineering News-Record's* representative, he

TOKIO'S IMPERIAL HOTEL, OF REINFORCED CONCRETE

brought out the following points regarding Japanese building practice:

For centuries past Japanese construction has employed stone masonry, brick, or wood and only recently has accepted American and European standards involving the use of structural steel and reinforced concrete. Of the latter two types of building, the steel frame structure has made the least headway, and it was only after a delegation of Japanese engineers was sent by their government to the United States in 1919 that negotiations for three large steel office structures in Tokyo were completed.

The reinforced-concrete structure, Colonel Starrett stated, found acceptance in Japan a dozen or more years ago. British and European influence was responsible, in part, for its popularity. For a number of years the trend of design was all toward reinforced concrete, and the building of the large steel structures in Tokyo, beginning in 1920, marked a new era in Japanese building practice. The steel frames of these structures were designed by Purdy & Henderson, engineers, of New York, in collaboration with Japanese engineers. In Colonel Starrett's opinion a factor accounting, in some measure at least, for the widespread use of reinforced concrete by the Japanese is that they came upon the necessity for buildings stronger and better than their old-fashioned methods afforded at a time when concrete construction was prominent in America and Europe. It was a simpler and more practical form for them to adopt and consequently was used in their first fireproof structures. Moreover, the science of steel design was not so well known and the difficulties of detailing and predetermination were very great. The Japanese fondness for decorative ceramic effects on the exteriors of their structures may have had some effect also. In zones subject to seismic disturbances Colonel Starrett points out that such considerations are of secondary importance, for during a severe shock decorative surface applications become detached and fall.

While the Japanese, according to Colonel Starrett's

observation, have been profound students of the causes and effects of earthquakes, it has only been during the last half dozen years that they have seen a clear analogy between the wind-bracing methods for steel structures common in American practice and bracing to resist earthquake shocks. Today, however, Japanese designers are attaching great importance to this feature of structural engineering, and the Tokyo office buildings above referred to are notable for their heavy diagonal bracing between columns and girders.

Earthquake shocks also have had an influence on Japanese practice in the design of steel columns. In the cases of columns consisting of successive lengths of steel members superimposed upon each other, the Japanese engineers place no value upon the bearing of the two surfaces against each other, but rely entirely on heavy splice plates, thoroughly riveted, for support at these column joints. This is a detail which was insisted on in the Tokyo office buildings.

OLD BUILDINGS ON YOKOHAMA WATERFRONT

The Oriental scheme of sway bracing, in its general features, is in accord with American practice, except that the wind loads assumed by the Japanese are many times the loadings on which calculations are ordinarily based in this country. Where an American engineer might assume a wind load of 40 lb. per square foot, the Japanese designer would base his calculations on 140 lb. per square foot. This results in exceptionally heavy sway bracing. Experience with earthquake shocks has shown the need for reinforcement of spandrel walls and substantial division walls to form stiff vertical plates throughout the structure.

Foundations—Subsurface conditions in Tokyo and its vicinity make important the subject of foundations for large structures. A large portion of the city is reclaimed ground and for a depth of 50 to 60 ft. below the surface the soil is soggy and swampy. Below the 60-ft. level sand is encountered, and below that, hardpan. Prior to the erection of the large steel office buildings some form of floating foundation was commonly employed in Tokyo, but in the case of the American-built structures the designs called for piers of concrete supported on piles extending down 50 or 60 ft. to a firm bearing. To accomplish this result it was necessary to import long timber piles from Oregon as local timber was too short and too small to penetrate to solid material. Colonel Starrett cited several cases where structures on floating foundations had settled a foot or more. The use of long timber piles in Tokyo, he pointed out, is under ideal conditions, inasmuch as the ground water

level is very close to the surface, so that there is no alternate wetting and drying with its consequent rotting of the timber.

Governmental building regulations in Japan limit the height of structures in the business districts to 100 ft., except where the material used is brick or stone, in which case a 65-ft. limit is imposed. Wooden buildings may not exceed 50 ft. in height.

* * *

Supplementing Colonel Starrett's discussion of Oriental building practice the following comment is based on statements by H. V. Spurr, chief engineer for Purdy & Henderson, consulting engineers, New York, who designed the three steel structures in Tokyo:

Foundations—The chief points in which the Japanese structures differ from American practice are in the foundations and column bases, the column splices, and the heavy diagonal sway bracing. The design followed assures an unusual amount of stiffness in the steel

DETAIL OF HEAVY SWAY-BRACING

frame. The knee-bracing consists of double channels, while there are both web and seat connections between columns and girders. The column splices, to which reference has been made, consist of four $\frac{7}{8}$ -in. plates and more than 200 rivets on each side, thus providing material considerably over and above that required for vertical loading. In one case the column splice extends the height of a full story of the building.

A feature of the foundation design is the reinforced-concrete struts which extend between column footings in perpendicular directions like the lines on a checker-board. These struts tie the whole pile-supported sub-structure together and are intended to add to the stability of the foundations in the event of earthquake shock. The columns are supported on special built-up bases through which, according to the desires of Japanese designers, anchor bolts extend into the concrete caps of the nests of long wood piles. These bases are equipped with wing angles to provide a connection with the reinforcing rods of the concrete struts and ties between foundation supports.

The spandrel wall details also provide for secure anchorage of terra-cotta or other facing material which might be shaken loose in the event of an earthquake.

* * *

Water Supply in Japan—While the interest of American engineers in the Japanese earthquake will undoubtedly center on the behavior of the buildings in the cities, there are other engineering works whose condi-

tion, after the disaster, should furnish data of great technical interest. Tokyo's water supply apparently has been severely damaged. The city, according to observations, made during a trip to Japan a number of years ago by Col. George A. Johnson, consulting engineer, New York, has had a public water supply of some sort ever since the year 1600, but it was not until 1892 that construction started on the present modern water-works system, which was completed in 1898. The original works were designed for 1,500,000 people and had a capacity of 45 m.g.d. Additions have been made to cope with the growing population which amounted, according to the 1920 census, to 2,173,000 people. The intake for Tokyo's supply is from the Tama River at Hamura, whence the water flows by gravity in canals, both open and closed, a distance of 30 miles to a filtration plant on the outskirts of the city. Here are located a battery of sedimentation basins (the original design provided for three, having dimensions of 360x720 ft. and 19.5 ft. deep). The settled water then passed to eighteen one-acre slow sand filters containing 30 in. of sand and 24 in. of gravel. They were designed to operate at a rate of slightly less than 3,000,000 gal. per acre daily, giving a capacity of about 53,000,000 gal. daily. Filtered water passed to three filtered water basins, each with a capacity of 7,500,000 gal.

During the time of Colonel Johnson's visit about two-thirds of Tokyo's supply was delivered by gravity to the low level districts and one-third was pumped to the high level areas against a head of 80 to 100 ft. by four 300-hp. pumping engines, each with a capacity of 7,500,000 gal. daily. Tokyo's water consumption averaged somewhat less than 20 gal. per capita daily.

Yokohama also installed a municipal water-works system in 1885, with an intake on the Doshi River and a 30-mile conduit delivering to a slow sand filtration plant.

Roads and Bridges—Press reports received in this country give scant information as to the condition of bridges and roads in the zone affected by the earthquake of Sept. 1. By the provisions of the Road Law passed in 1919, highways in Japan are classified under five subdivisions: (1) national; (2) prefectural; (3) district; (4) city; (5) village. On this road system, according to the 1921-22 edition of the "Japan Year Book," there are 346,144 bridges, of which 518 are metal, 71,258 stone, and 136,860 wood. In addition, there are some pontoon structures and others of a type not classified.

Japan has about 1,000 harbors, large and small, of which about 60 are open to foreign vessels. Yokohama, where the effects of the earthquake are reported to have been particularly severe, is one of Japan's leading seaports. The engineering works at this port include training walls and piers.

Railway—Prior to 1906 the railways of Japan were operated by a number of companies independently. In that year the railways were nationalized, and seventeen lines, with about 3,000 miles of track, were consolidated into a single system. Extension has been made since that time and in 1920 the mileage of Japan's railways is reported as 6,000. As the capital of the Empire, Tokyo is an important railway terminal. The station is located near the Imperial Palace and is a brick and steel structure about 1,100 ft. long with a maximum width of about 140 ft. The dome of the station is 124 ft. high.

Notes on Roads in the Orient

Observations on a Trip in China, Japan, Ceylon and the Malay States—Modern Machinery Seen But Manual Methods Predominate

BY W. W. CROSBY

Superintendent, National Park, Grand Canyon, Arizona

ONE LESSON again impressed on the writer by his recent observations of road work in the East is the adequacy of quality to make up for lack of quantity. The road authorities of the East have demonstrated the efficacy of simple methods and moderate expense to meet the needs of their traffic developments. They have not set up the golden calf of quantity production nor have they neglected for a moment the proper devotion to maintenance. And they do not chase any will o' the wisp of "permanent roads."

City Pavements in China—What can be called roads do not exist outside of the immediate vicinity of the cities of China.

A brief inspection in Shanghai revealed streets in good condition though practically wholly of macadam.

FIG. 1—OX-CART AND AUTOMOBILE BOTH TYPICAL OF CEYLON TRAFFIC

Some have been treated with bituminous material. The maintenance is excellent but the methods are antiquated in instances. One repair gang was seen using as a roller a stone cylinder, pulled by 21 coolies on the draft-ropes.

Canton has few paved roads or streets as we know them. In fact but few roadways for wheeled traffic have been opened up in this curious city. The recent demolishing of the old city walls is leaving some strips of ground for development into streets, but the public highways of Canton are mainly only narrow alleyways between the shops. They are from 4 to perhaps 10 ft. wide, paved with slabs of stone, and usable only by pedestrians and "chairs" carried by coolies.

Rickshas use only the few streets available for them and consequently their employment is over a very limited area. Further, the roughness of the unpaved streets renders riding in wheeled vehicles most uncomfortable and only warranted by their greater speed. The coming of the automobile is tending to bring about some road developments. Even if some roads shall be built, however, the problem of their maintenance is a most serious one. The translation of funds into roadways can be conceived, but no one who knows conditions in China can conceive the raising of funds for road maintenance after construction and then the securing of the work from these funds. Possibly a toll-road company might be operated successfully, assuming a stable government to exist in any section, but the reputations of Chinese officials for "squeeze" prohibit any hopes for good roads in China from public official sources.

FIG. 2—TYPICAL TRAFFIC IN ADEN

Hong Kong's streets and roads are well paved with bituminous surfacing, mostly penetration macadam. In both Shanghai and Hong Kong steam-rollers were seen but even in Hong Kong the stone cylinder pulled by man-power was at work on repairs. While the types and methods of road work in these cities seem rather primitive, the good results everywhere noticed bear witness to the excellence of the work done even in these ways.

The wheeled traffic in China is light, but the use of the motor car is rapidly growing and already a considerable number are evident in Shanghai and Hong Kong, with a few in Canton.

In the Malay Peninsula—The roads of the Federated Malay States are apparently sufficient for their traffic and are well maintained. They are frequently of water-bound macadam and in some cases treated with bituminous material. The macadam is excellently laid and in the moist climate well maintained under what we would call light traffic, mostly rickshas, ox-carts, and passenger automobiles. The heaviest of the last are buses carrying eight or ten persons.

The macadam is of the English type, quite thick, say 8 to 10 in. or even 12 in., frequently with a sort of Telford base, and is well consolidated by steam-rolling. The bituminous treatment is generally carpeting the consolidated and completed macadam with hot bituminous material and grit after the road has been opened to traffic.

A section of old macadam that was really worn out was seen undergoing resurfacing. The new macadam layer was being placed at least 8 in. thick on top of the old roadway and steam-rolled with the aid of water to

FIG. 3—MAINTENANCE GANG REPAIRING WATERBOUND MACADAM IN JAPAN

blind it. Traffic was then turned onto the new surface for a period after which the traffic was again diverted, the surface thoroughly swept and cleaned even by using hand scrapers to remove the last vestiges of adherent matter, and the hot bituminous material was evenly applied and swabbed onto the roadway surface. A coating of sand was then brushed evenly over all and the traffic was readmitted. The results were excellent.

In another place near Singapore some minor repairs were being made to a bituminous roadway as follows: The depressions or chuck-holes in the old macadam were loosened by hand-picking to a depth of about 2 in., with fairly vertical edges, and all the old material was cleaned out. Fresh metal, which had been previously coated with bituminous material, and of which piles existed along the edges of the road ready for use, was then placed carefully in the holes and conformed to the adjacent road-surface by raking and tamping, and this patch was then coated with sand and the traffic permitted on it. Again the results were excellent.

It may be noted that the above described patching is identical with work noted by the writer in Leamington, England, in 1908 and that the same care seems to be taken with small details in Malay road work that is evident in the good work done in England and France. It may be that this carefulness underlies the success of what some might now call antiquated methods in meeting the demands of traffic developments during the past fifteen years.

In the city of Singapore there are many excellent streets. They are wide, well-located, and generally well-surfaced. Bituminous material prevails and it is understood to be largely used in the more superficial methods. Some mixtures have been laid, and the writer had the pleasure of meeting the local representative of our old friend, The Barber Asphalt Co., which is engaged in introducing that standard sheet-asphalt pavement to the Malay States with some success.

One stretch of cement-concrete pavement was seen being laid in Singapore. The construction was truly British—substantial to say the least. It was reinforced near both the top and the bottom, in both directions, and the two layers of reinforcing rods were united by vertical wires or rods. Possibly there were to be also diagonals but they were not in place at the moment. Evidently openings through this pavement were not contemplated soon nor was any surfacing to the concrete apparently provided for.

In the smaller places such as Kuala, Lumpur and Penang, bituminous surfaces in excellent condition prevailed for the streets, and waterbound macadam, equally good, outside except possibly on some of the more popular routes, which were surface-treated with bituminous material.

Ceylon—Traffic around Colombo is extraordinarily varied in character. Rickshas, Rolls-Royce cars, racing-sulkies drawn by one trotting-bullock and a two-wheeled prairie-schooner type of carts drawn by a pair of diminutive oxen, tin-Lizzies and regular steam-lorries from Hold Hengland pulling one or two trailers, a few horses, both saddle and draft, with electric trolley cars on rails are all to be seen on the streets or roads adjacent to this beautiful city.

Again the bituminous-surfaced roadway prevails and is everywhere in good condition. In one wide street a strip of stone blocks along each side next to the curb furnished a roadway for the slow moving animal-drawn

traffic. Out in the country some waterbound macadam roadways are in excellent condition.

The maintenance of all the roadways seems promptly and well done. Apparently the use of bituminous surface-treatments is gradually but steadily extending.

The methods used here are those before described for the Malay States but perhaps the tools and machinery or means used in the Ceylon work cover even a wider range. Steam-rollers are numerous. With them work sprinkling wagons or carts consisting of a cylindrical iron tank holding perhaps 150 or 200 gal. of water and drawn by a pair of miniature oxen with their native driver almost always squatting on the pole. Workmen, with their curious long-bladed hoes, scrape the stone free from piles along the roadway into flat scoop-like baskets and carry it to the holes to be patched. One pair of workmen squatted beside a hole some 2 ft. square pack the new metal into it with their hands and sift through their fingers the old material just taken

FIG. 4—JAPANESE MAINTENANCE MAN FILLING A CHUCK HOLE

from the hole, in that way obtaining enough fine material for binding the patch.

The carrying of materials for road work in baskets at each end of a pole across the shoulders of men and women is not quite as common as in Japan but nevertheless prevails even with the bullock-carts seemingly everywhere at work.

The coolie-drawn stone roller was not evident around Colombo but another novelty to American eyes is to be seen in the shape of a stone cylinder drawn by an elephant. Possibly the combination of tamping and rolling effects thus secured is peculiarly beneficial. At any rate the most critical would be pleased with the present roads of "beautiful Ceylon's Isle."

Aden a British Outpost—Here the few roads are British waterbound macadam, well built and well maintained. The steam-roller is again a familiar object but the vehicle traffic is less familiar to American eyes. The most striking vehicles are camel-drawn carts. These seem numerous about the town, in fact they predominate though passenger motors are plentiful.

A curious sight were the road-sprinklers skillfully slopping water from leather bags, slung by a strap over their shoulders, onto the roadway to lay the dust.

Japanese Roads Inadequate—For the traffic of the past, peculiar to its locality, the roads of Japan have undoubtedly sufficed. For their present traffic they are made to answer, extravagantly, probably, in many instances. For the future, the existing roads cannot be considered "good" from the angles of economy, sufficiency or satisfaction to their users.

In the main the roads are too narrow for modern

traffic, too crooked, and too crudely surfaced. In such cities as Kyoto, Osaka, Tokyo, Yokohama, and Kobe many splendidly wide streets exist, but, except in the last two or three places named, scarcely any paving of a modern type is evident. The surfacings, even in the cities, are a sort of macadam made of gravel (or broken stone) without proper rolling and with an excess of fine material to bind the metal. The result is the familiar old one of a soft muddy or dusty road that ruts easily and wears into "chuck-holes" readily.

The maintenance of the more important roads and streets is very good. Apparently labor is plentiful, for a maximum amount of hand work is employed. Gangs are seen constantly at work patching the chuck-holes with broken stone or gravel and spreading fine material over the loose stone so that it may bind down under the traffic.

The writer was fortunate enough to observe such a repair gang at work on The Bund (the waterfront street) of Yokohama one rainy day, and the photographs show the picturesque workmen in their straw rain-coats, some of their implements, and methods.

Some of the men are picking off the bunches in the macadam surface; others are moving stone in a two-wheeled barrow or cart from a large pile alongside the roadway to smaller piles more frequently placed within it (as far as the photos go these latter workmen are "off stage"); others are taking the stone from the small piles to the holes in the roadway in wooden trays. The picture of the single man shows him using the tray and filling a hole. This gang worked industriously and intelligently without argument or unnecessary conversation, which seems worthy of note.

Tokyo has one main street with some good wood-block pavement. Kobe has considerable good bituminous pavement, chiefly of penetration type, as has Osaka.

The street railways, which seem to be astonishingly numerous and popular, in the cities mentioned, are of the "double trolley" type and up-to-date, except that the cars are too small for the crowds they carry. The railway areas are generally well paved with rectangular slabs of stone about 4 in. thick, closely jointed, and from 12x18 in. to 18x30 in. in area. These pavements are generally kept in excellent condition even where the adjoining roadways are of the macadam above described.

In Tokyo some modern road machinery was noticed such as an asphalt roller, a macadam roller, and an elevator with spiral fins or vanes at the base for loading metal from piles on the ground. On the other hand, in Nara a section of road was being repaired and the broken stone was being rolled or consolidated in place by the traffic plus the operations of a stone cylinder about three feet in diameter by four feet long hauled back and forth by five oxen hitched tandem to it.

Wood Preservative in Bored Holes

Marine borers cannot be repelled from piles, poles or other timbers by filling bored holes with a solid preservative. Tests have been made by George M. Hunt, Forest Products Laboratory, as reported in *Wood Preserving News*, on longleaf sap pine specimens 2 ft. long and 6 to 8 in. in diameter bored with 1½-in. holes along the axis. About ½ lb. each of three chemicals, lead nitrate, sodium fluoride and arsenic were tightly corked into the specimens. After 14 months in salt water at Pensacola, Florida, inspection disclosed that the specimens were riddled by shipworms.

Making Meter Maintenance Pay Big Dividends in Texas

INCREASED income from a water-works plant from meter maintenance is seldom looked at from the dividend standpoint and in consequence the figures given below, of the results obtained at Cleburne, Tex., are of particular value. J. W. Hockaday, superintendent, water and sewer department, read the data at a meeting of the Southwest Water Works Association.

Referring to the table, two changes took place in 1917, more meters were installed and more money was spent in maintenance. All of the increase in revenue is credited to meter maintenance because the records show that the

TABLE—RESULTS IN REVENUE DIVIDENDS FROM MAINTENANCE OF METERS IN CLEBURNE, TEXAS

Date	Million Gallons Pumped	Meter Maintenance Cost	Number of Meters	Return On Each Dollar Paid Out For Maintenance	Total Revenue	Increase in Revenue

* Of this amount \$1.75 was for increased revenue and \$5 for decreased operating expense.

efficiency of the plant was not kept up, in fact it fell for several years. Attention is called to the fact that new meters installed do not need maintenance the first years of service. The record for 1919 shows new changes, higher efficiency and increase in revenue with a falling off in pumpage.

As in all cases where changes are made, new complications show up and the operators in 1920 were in a quandary. With an increase in revenue and a decrease in pumpage, the future looked bright, but what disappointment came when at the close of the year the pumpage had taken an airplane trip, while the revenue had gone on a long, long toboggan slide. Rejoicing satisfaction had been turned to disappointment and chagrin. It was determined not to install any more meters. It was figured that while the flat rate prevailed, the revenue was more and the pumpage less than with meters, therefore the conclusion was easily reached and the meters were condemned. This policy is shown by the small amount of money spent to maintain the meters. It was not known that this lack of maintenance was the cause of the whole trouble. Nor was it realized that the meters installed several years previous were slowing up, and that the meters recently installed needed investigation to learn if they too were under-registering. Anyway, the trouble was charged to the meters; practically nothing was done to maintain them and no more meters were installed.

In the first six months of the following year the system was completely metered and a meter maintenance crew was organized; in the last six months of the year \$2,235 was expended for meter maintenance. A marked change took place in the revenue column. Confidently entering the year of 1922, the greatest sum yet was spent for meter maintenance. The end of 1922 showed an increase in revenue of \$1.75 for every dollar put into maintaining the meters and a remarkable decrease of \$5 in operating expenses.

Possibly this paper should stop right here but the above is not all the story. When efficiency was at the lowest point, it was clearly seen by those who know the situation that the water supply was fast failing. The officials began to cast about for another water supply, and talk of a large bond issue was indulged in. The raising of the efficiency brought this department from a losing to a paying proposition, so that now this same department can swing a bond issue in such a way that it will not cost the people one cent for a new water supply. It is the right thing to install meters, but the battle has just begun then. The meters must be maintained.

Hints That Cut Cost and Time

For the Contractor and the Engineer

Connecting New 60-M.G.D. Pump Sections To An Existing Wet Well

IN CONNECTING two new 60-m.g.d. steam turbine-driven centrifugal units of the Springfield Avenue pumping station, Chicago, to the wet well, a shaft was sunk directly under the pump and a tunnel, 15 ft. long, was driven to the existing pump well. Before work started on the tunnel a sluice gate was set in the old well on a block of concrete over the location of the outlet of the proposed tunnel. With the gate shut the tunnel could then be driven, lined and all connections made

rows of five "primers" each, outside of which are the rows of "helpers" (four each). Sixty per cent dynamite in 1-in. sticks was used and peeled off about 18 in. at a shot. The bellmouth pump sections were concreted into the shaft over the end of this tunnel making a sealed connection 9 ft. below low water surface.

A sidelight in operation developed shortly after starting these new units in the way of complaints regarding fish in the mains. In winter the screens in the crib in the lake supplying this station are lifted because of difficulty with ice. With the centrifugal pumps the fish came through unharmed and appeared at hydrants and faucets. A rectangular screen cage $6\frac{1}{2} \times 9\frac{1}{2}$ ft. in plan, 40 ft. high, with the four sides covered with $\frac{1}{2}$ -in. mesh No. 12 gage bronze wire screen, was built of angles and plates in the well over the end of the upcoming tunnel. Spring plates 8×12 in. long were riveted to the angle at the base of the cage to effect a tight joint. The velocity through the screen at the rated capacity of the station, 120 m.g.d., is 1.2 ft. per second. The wider screens weigh 2,000 lb. All ice is melted by the time it arrives at Springfield Avenue, but the fish do not disappear and it requires one man continually netting them out of the screen chamber. Formerly they undoubtedly went through the pumps and appeared, if at all, as "fish chowder."

The installation of the new pumps is under the supervision of Alex Murdoch, city engineer.

DRILL-HOLE SCHEDULE FOR SUCTION TUNNEL,
SPRINGFIELD AVE. PUMPING STATION

Note the close spacing of "primers" and the rows of "helpers." Holes were drilled 24 in. deep but only about 18 in. was peeled off at a time.

without unwatering the wet well which had to be kept in service for the other pumps.

On account of the close quarters and the proximity to the pumping machinery above, only small shots in closely spaced holes in the tunnel heading could be used. The $\frac{1}{2}$ -in. holes were drilled by jackhammers, 2 ft. deep and about 12 in. apart, with four rings in the top half and three rings in the lower half. The photograph of the heading was taken after the last shot had been made and shows the drilling just before starting to use bull points to break through the last foot back of the sluice gate. About the same spacing was used for shooting except for the four holes between the two

Water Increases Delivery Radius for Gravel Handled in Chutes

IN FINISHING up some of the fills placed in connection with the Ballantyne Pier at Vancouver, B. C., the contractor found it expedient to bring the material in on barges and to unload it by means of a grab bucket also on floating equipment. Part of the area to be filled was out of reach of the boom on which the grab bucket operated and the contractor therefore constructed a hopper or small bunker within convenient reach of the grab bucket boom and at such a height that a chute or flume could be led from the hopper on a 1 to 2 grade to the farthest point to be filled.

From equipment on hand, a pump was rigged up to deliver water through a 3-in. hose into the lower end of the bunker through a nozzle directed downward into the head of the flume. Material already on the job, chiefly "leftovers," was used for constructing the hopper and the flume, and the lower end of the latter was arranged to be shifted conveniently so as to facilitate even distribution of the fill.

As the fill sloped directly into the tidewaters, there was no drainage problem and the pump was allowed to run continuously. Under this program, as fast as the material was dumped into the hopper it was carried rapidly down the flume to the desired position in the fill; in fact, a much flatter grade could have been used had this been necessary.

The contract is held by the Northern Construction Co. of Vancouver, of which William Smail is chief engineer.

Carrying Heavy Loads Over An Old Wooden Bridge

By E. C. SEIBERT

Lieutenant, C. E. C., U. S. Navy, U. S. Veterans' Hospital, Gulfport, Miss.

DURING the progress of 5,000 marines from Quantico, Va., to Gettysburg, Pa., last summer, a bridge over Tom's Creek was encountered near Emmitsburg, Md., which was of interest to the officers for the primary reason that it held up the progress of the 3-mile train (supplies, ordnance, equipment, etc.) because of its inadequate strength. Further, it was of a fast disappearing type, so old as to be curious. It is a statically indeterminate truss-and-arch combination of approximately 66-ft. span, with a shingled gable roof and with covered sides, forming a through bridge. According to a native, its age is 80 years. It is built of white pine, which, above the floor system, is in a very fair state of preservation, considering its age, its chief defect being

FIG. 1—OLD WOODEN BRIDGE AT EMMITSBURG, MD.

the presence of numerous small shrinkage cracks in places. However, the west arch has been broken a few feet from the north abutment, the floor system is badly rotted, and much of the roof and siding has disappeared.

The bridge has been kept standing by the placing of a bent about 14 ft. from the north abutment (near the crack in the arch) and by several posts under the middle stringers, as shown in the drawing. These crude repairs, in effect, converted the bridge into a hybrid of trestle, truss, and arch. According to signs on the bridge, the maximum load allowable is 8,000 lb. This was being exceeded daily. When any load heavier than a touring car passed over, the deflection of the bridge was very noticeable, amounting to several inches in some places. The maximum deflections were reached when the "floating" props under the stringers came up hard against the creek bottom. Upon the advent of the marine train at the bridge, some of the lighter loads were allowed to pass, and part of the train laid by until a portion of the engineer company hastily put in some 8 x 8-in. props, wedged in place. The heaviest loads (tanks, tractors, mounted shops) were detoured several miles over a wrought-iron bridge.

On the return of the marines from Gettysburg, the

FIG. 2—TRUSSES SUPPORTED ON POSTS TO CARRY ARMY TRAIN

above-mentioned detour having been by rains rendered practically impassable for the heavy equipment, an engineer company was sent in advance of the main body, and in 6 hr. completed the bracing shown in the view, enabling the entire train to pass with safety.

The members of the bridge are connected by wooden pins, except at the points of intersection of the arches with the trusses and at the intersections of the top laterals, where hand-made iron bolts are used. At the panel points the posts run between the two timbers constituting the chord, which are mortised into the post, thereby making the strength of the joint dependent upon the shearing strength of the timber along the planes *a, b*.

The portals of the bridge are architectural in character, of simple, classical lines. The bridge is a good example of an honest product, the combination of good craftsmanship and wonderfully excellent materials. The writer has never seen recently produced timber which in his opinion would live half as long as has the pine in this old bridge, under similar conditions of service.

Steam Shovel Used to Break Up Tough Wood for Own Fuel

DURING the coal strike early this year which threatened to cut off certain Cuban industries from their supplies, a steam shovel was impressed into service to break up, for its own uses, a species of native buckthorn. No ordinary axe would cut the wood, so G. R. Buchanan, manager of the Cape Cruz Co., of Ensenada de Mora, rigged up the shovel in such fashion that the gang of laborers available was not able to feed the shovel fast enough.

Using an old mill coupling with an 18-in. square opening to take a wedged-shaped broken piece of 17-in. mill shaft, a hammer was rigged to operate in leads made of lengths of old rails. The shovel bucket was used to hold down the ends of the sticks so that they would not fly up when being broken.

With this arrangement 13,054 tons of buckthorn were broken into cordwood lengths at a total cost (which included reloading into cars and unloading into storage piles) of \$26,065, or a trifle less than \$2 per ton.

The information from which this item was written was supplied by the Marion Steam Shovel Co., Marion, Ohio.

Automatic Sewage-Flow Regulator for Intercepting Sewer

By H. S. PHILIPS
Engineer of Sewer Design, Hamilton, Ont.

A SEWAGE-FLOW regulator to prevent excessive discharge to an intercepting sewer during storm periods has been designed for the Barton St. trunk sewer, Hamilton, Ont. The drawing shows a 54 x 63-in. cunette sewer with a 54 x 51-in. overflow to the Kenilworth Ave. storm sewer and a 24-in. intercepting sewer; also an overhead 15-in. sanitary connection from the Kenilworth South combined sewer, brought to one chamber to avoid duplication of manholes.

The cunette is designed to carry $1\frac{1}{2}$ times the maximum dry-weather flow when the drainage area is fully developed. This flow will discharge through the normally open regulating gate until the volume increases so that it overflows the berm. As the flow passes the screened orifice, it is diverted to the float chamber,

WALKING-BEAM TYPE OF SEWAGE-FLOW REGULATOR FOR INTERCEPTING SEWER AT HAMILTON, ONT.

which causes the float to rise and gradually close the gate.

The float chamber has been placed downstream so as to avoid, as much as possible, the offensive deposits which would be formed if the float were placed in the dry-weather flow channel.

The regulator is of the walking-beam type, and consists briefly of a segmental gate valve and a float of the diving-bell type, entirely of cast iron and bronze. The float is 30 in. in diameter and 13 in. high, of $\frac{1}{2}$ -in. metal reinforced by ribs. A lead and a bronze washer are used at the joint between the float and rod, which necessarily has to be airtight. The float is constructed of cast iron in preference to brass or copper on account of the leaks which develop in these sooner or later. The instability produced by the center of gravity of a bell of uniform minimum thickness being above the center of gravity of the liquid displaced is met by partial suspension of the float from a rigid point as high as possible above the bell. The float is counterbalanced by weights on the gate-valve rod, added as required.

The cast-iron gate valve and fittings are of conventional design, having cast-iron faces with $\frac{1}{2}$ -in. clearance, and the gate arms are fitted with bronze bearings. The connecting arms are of $\frac{3}{4}$ -in. bronze rods with a cast-iron link holed for different adjustments on the float side. A simple universal joint of cast iron with bronze

From Job and Office

Hints that Cut Cost and Time

tube bushings is placed on the gate connecting rod.

The screen to the float chamber is made up of $\frac{1}{2}$ -in. diameter bronze wire on a $\frac{1}{2}$ -in. diameter diamond mesh with a $\frac{1}{2}$ -in. diameter bronze frame, and is secured to walls by a $\frac{1}{2}$ -in. diameter bronze clamp.

Large Relief Map Used to Lay Out Logging Railway System

IN PLANNING the woods operations of the Long-Bell Lumber Co. in Washington a topographical map was first made of a 133-sq. mi. tract of land on which the timber stands. Three duplicate relief maps were then made up on a vertical and horizontal scale of 200 ft. to

the inch. Different colors were used to indicate different densities of stands, aerial cables were located by threads between pins, and threads on small tacks indicated projected railroads. Telephone lines, roads and other features of the development were also shown. In this way the relief map has proved a great aid in visualizing the scope and plan of the operations. Of the three duplicate maps one is to be kept at the woods headquarters as an aid in visualizing operations, the second will be kept at company headquarters to aid in projecting work in advance, and the third will be sent to the eastern headquarters of the company.

About 250 men were employed in making the field survey. Parallel lines were run through the entire tract, 440 ft. apart in a north and south direction, and, in addition to the section lines, east and west lines were run through to connect quarter-section points. A relief map was made by tracing each 10-ft. contour on cardboard and then cutting the cardboard to the outline of the contour. Each square mile was built up separately, the cardboard sections being glued together on a one-piece wooden base whose lower surface was an assumed datum below the lowest elevation in the tract. When all the sections were assembled the resultant map of somewhat irregular shape occupied an area 25 x 36 ft. The plotting of the notes and the assembling of the sections kept occupied a corps of about 25 men for six or seven months.

Simple Formula Solves Vertical Curves

By STANLEY J. NICHOLS

Civil Engineer, Troy, N. Y.

RECENT park work on which I was engaged involved extensive use of vertical curves. Textbook

FIGURE FOR SOLVING VERTICAL CURVES

methods of computation proved rather tedious, so the following analytical formula was developed.

$$c = \left(\frac{d}{L}\right)^2 D$$

where c is the offset; D , the distance from the P.C. to the point of offset; L , the length of curve, and d , difference in elevation of the P.T. and the point B' . Then

$$c_1 = \left(\frac{25}{250}\right)^2 7.5 = 0.075$$

$$c_2 = \left(\frac{50}{250}\right)^2 7.5 = 0.300$$

$$c_3 = \left(\frac{75}{250}\right)^2 7.5 = 0.675$$

In this case the offsets are subtractive, the curve elevations therefore being found by subtracting them from the elevations along the tangent line.

Breaking Up Old Concrete by Hydraulic Pressure

By MAJOR JOHNSTONE-TAYLOR

Lymm, Cheshire, England

REMOVAL of old concrete is often difficult and costly work. Use of hammer and wedge is slow and laborious. The work is often in a confined or populous area and the use of explosives might be dangerous, or even prohibited. Hydraulic power can often be turned

HYDRAULIC RAM FOR BREAKING CONCRETE

to good account in this direction through the medium of a simple tool, the hydraulic mining cartridge.

Referring to the sketch herewith: pressure cylinder A has fitted to it, rams B . It is connected by steel pipe C to pump D . The plungers of the pump are operated by screws E and E' , to which are attached handles F and F' . The tank G holds about a quart of water,

cylinder A and piping being first primed. After this is done pressure is applied by the large handle and screw and final pressure by the small handle and screw.

The average pressure obtainable is 4 tons per square inch, and the machines are made with five, six and eight rams, the largest size, which is 4 in. in diameter and has eight rams, can exert a pressure of 240 tons. This pressure is used to split up the concrete or other mass into large blocks.

To operate a hole is first drilled. For a 4-in. machine this would be a 4-in. hole, some 36 in. deep. Into this is inserted the tool, the faces of the rams bearing on little plates of 3-in. flat bar. It will be seen that the tool itself is very simple, but it requires machining from very strong material.

The arrangement of the pump shown here is not binding; provided sufficient pressure is available it can be obtained from a high-pressure hydraulic supply if handy, or from an ordinary hand-pressure pump of the type used with tire and axle presses. Generally speaking, however, a pressure of from 3 to 5 tons per square inch is required.

Repairing 20-in. Water Main With Sleeve That Was Too Small

By MCKEAN MAFFITT

Superintendent Water-Works and City Engineer, Wilmington, N. C.

IN SETTING a 20-in. valve in a main we made the mistake of cutting our nipple pieces too short so that when we went to put on the sleeve there was a space of 7 in. between the ends of the pipe. To further com-

BUSHING AND LEADITE USED TO MAKE UP FOR TOO SHORT NIPPLES AND TOO SMALL SLEEVE

plicate matters the only sleeve that we had in stock was so small that it would barely slip over the pipe, not leaving enough space to get a yarning iron in.

The water was off, the pipe was cut, and something had to be done and done at once. This is what we did:

A bushing of heavy galvanized sheet-iron was made with an outside diameter of 20 in. and a length of 12 in. This was slipped inside the 20-in. pipe so as to bridge the space left between the ends of the pipe (see sketch). The space between each pipe end and the outside of the bushing was filled with fire-clay, the sleeve having been forced back for the purpose. The sleeve was then driven back to position and a 1-in. hole was drilled through its middle. The outside spaces at both ends of the sleeve were filled with fire-clay and the remaining space was poured with leadite which made a filler between the ends of the pipe and between the sleeve and pipe and gave us a watertight joint.

The only trouble we experienced was in getting the sheet-iron bushing to fit and in moving the sleeve over the pipe. The sleeve fitted so tightly that we had to use a sledge in driving it along the pipe.

Suspended Track Solves Overburden Disposal Problem

OVERBURDEN covering clay deposits being worked by the Adel Clay Product Co., of Adel, Iowa, is being disposed of easily and inexpensively through the use of the suspended track pictured herewith. To handle the overburden, which ran to an average depth of 14 ft., with men and teams was considered too expensive, so the structure shown here was constructed.

The loaded dump car runs over standard track from the clay pit to the point where the waste material is to be deposited. Here the track is carried out over a ravine by means of two 1½-in. steel cables, 640 ft. long, that run to a tower 40 ft. high and are securely guyed. The ties that carry the suspended track are swung 30 in. below the main cables through the use of hangers;

DUMPING EARTH FROM SUSPENDED TRACK

these maintain the center of gravity below the cables. A bumper is provided to stop the car at the right point. The car weighs about 5 tons and handles a load of about 10 tons. One difficulty in tightening the cables was met by providing a four-lug clamp to hold the turnbuckles; a bent tube is used for turning them.

The former cost of about 30 cents per yard for disposing of this overburden has been reduced through the use of this device to a small fraction of that figure.

Repairing Leaks in Concrete Tank When Subjected to External Water Pressure

BY R. W. HORNE

Pay, Spofford & Thorndike, Consulting Engineers,
Boston, Mass.

ABOUT three years ago the writer served as resident engineer upon the construction of a concrete fuel oil storage tank of about 2,500,000-gal. capacity. This tank was constructed in made land where it was subject to hydrostatic pressure from tide water, the head of water at high tide amounting to 15 to 20 ft. Inspection of the tank previous to filling it with oil showed a few instances where tide water was leaking into it. As there was to be no special waterproofing treatment of the concrete other than the use of a 1:1½:3 mix throughout, it was very important that all leaks be made absolutely watertight.

In repairing the leaks the method followed was to cut away the concrete to a depth of 2 or 3 in. in the vicinity of the leak until the vein through which the water entered was definitely located. The area over which the concrete had been cut away (sometimes amounting to 3 or 4 sq.ft.) was then repaired with a rich mixture of mortar made with quick-setting cement.

From Job and Office

Hints that Cut Cost and Time

It was soon found that in order to get a tight patch it would be necessary to relieve the water pressure from the fresh mortar until it had "set up"; otherwise the leakage was certain to find an outlet through the patch.

The additional precaution was therefore taken to relieve the water pressure by the use of pieces of ½-in.

wrought-iron pipe a few inches long, which were plastered into the patch adjacent to the leakage vein, thus giving leakage water a free outlet through the pipe and obviating all chance of hydrostatic pressure upon the patch. When the patch had become thoroughly set, the opening through the pipe was tightly calked with lead wool, thereby effecting a patch which was certain to give no further trouble.

These patches were made in various parts of the tank which has now been in service for about three years without showing any evidence of further leakage.

Dish-Pan Reflectors Are Effective and Economical

USE OF galvanized-iron dish-pans as reflectors for illuminating night work on the Big Creek project of the Southern California Edison Co. has been most successful. Around the power house site or in the

tunnel camps where a permanent location is possible the dish-pans are simply nailed to some convenient post or structure after having been wired for the desired number of sockets.

The type shown in the illustration is for portable use along the penstock line. In this case the dish-pan is bolted to a 7-ft. length of ¾-in. steel rod, the lower end of which has been sharpened. A reflector of this sort served by a flexible cord can be moved about as desired and thrust into the earth at any convenient point. Two to four 150-watt lamps in this reflector give a broad beam of good light. The cost is very low and when bent or otherwise

PORTABLE REFLECTOR FOR LIGHTING NIGHT WORK

damaged the dish-pans can usually be bent back into shape and made serviceable again.

Pocket Electrical Device for Measuring Water Depth in Wells

By J. M. C. CORLETTE

Water Supply & Sewerage Board, Newcastle,
New South Wales, Australia

DETERMINATION of water level in wells and pipes has been achieved in various fashions, but the simplest, perhaps, that the writer has seen is described in the following paragraphs. This device was used in accurately determining water levels in $1\frac{1}{2}$ -in. pipes sunk into sand beds from which water was being drawn by pumping.

It consists of a small pocket compass, a couple of dry cells ordinarily used in small cheap pocket electric torches, and a solenoid made by winding fine insulated wire on a cotton reel. One terminal from the cells is connected by insulated wire and a clip to the pipe in which the depth has to be ascertained. The other is connected through the winding of the solenoid to a suitable contact plate which can be lowered down the pipe, being kept insulated from the walls of the pipe. It is suspended by insulated wire and a measuring tape.

In taking levels the box carrying the compass is placed so that the needle of the compass lies transversely to the axis of the solenoid. On lowering the contact a current flows through the solenoid at the instant the water is reached and the magnetization produced results in a vigorous "kick" of the needle of the compass.

The cells used were about $3 \times 2\frac{1}{2} \times \frac{3}{4}$ in., and one was found to be sufficient, though two in series are shown, and they last at least three or four months, with fairly constant use.

The type of contact terminal can, of course, be varied from that shown herewith. One used successfully consisted of a piece of hardwood in the side of which a groove was made to house the insulated wire which continued to its end where it was soldered to a smoothed half-penny piece. It is necessary for the terminal contact to have a fair surface area to get good results.

If the compass is luminous it will be more handy for night work.

The apparatus as used was only roughly made up but gave accurate results over a long period. It would be easy to make it up in compact form to fit the pocket.

ELECTRICAL SET FOR
DETERMINING WATER
DEPTH

Stone-Filled Cage for Protecting Bridge Piers.—A method of protecting bridge piers from underscour which John B. Leonard of San Francisco has used effectively for a number of years is the construction of a stone-filled steel cage around the pier. Railroad rails are driven around the pier about 15 ft. out, and 18 in. apart. Usually these rails are about 20 ft. long. The space inside the rails is filled with niggerheads or any available rock that has rounded corners—sharp rocks have a tendency to wedge and defeat the purpose of the arrangement. When scouring action begins, the smaller rocks, which are always put in first, move toward the affected portion of the cage and effectively prevent the scouring action from getting inside the line of the rails. At the top of the cage, where there may be considerable movement of the filling, the individual stones are too large to pass between the rails. The smaller ones used in the lower portions of the cage are held by the weight above.

Precast "Brick" Lintels.—In a building in lower New York City, where building alterations necessitated changes in the positions of windows, lintels, made of precast concrete pieces, were used. The concrete was colored with a pigment to simulate the color of adjoining brick. Joints were cast in the concrete and, after the lintels were placed, pointed with mortar to match the old joints. As the walls where those precast lintels were used were not bearing walls the concrete pieces did not have to have any particular structural strength, though it would have been possible to reinforce them properly if they had been subjected to stress imposed by a bearing wall. Saving in time and labor by using the precast lintels was considerable.

Inexpensive Circular Tank Forms.—On a job involving the installation of two 6-ft. water tanks, 30 ft. long, in New York City, the contractor devised a unique method of fitting circular formwork used in placement of concrete forming the supporting walls at either end of the tanks. Plates cut to proper radius were made up of scrap black iron of about No. 18 gage, four or five of these plates forming the required circle. The form boards were cut with square ends nailed to the studs in such a manner that the space between the square end of the form board and the outside of the tank was not over 2 in. The sheet iron pieces were tacked to the inside of the form. The only fixed dimensions on the sheet metal were the 2-in. width at the narrowest portion, and the radius to fit the tank. Contractor's Atlas reports a saving of \$4 a yard in the placement of concrete with such formwork.

Steel Bars Tie Curb and Gutter to Pavement.—In order to secure true line and pleasing finish, and at the same time the structural strength resulting from constructing concrete curb and gutter integral with the pavement, the engineer in charge of paving at Libertyville, Ill., has employed unusual means. The curb and gutter have been constructed first, but with $\frac{1}{2}$ -in. round steel bars set in the curb at 3-ft. centers and projecting perpendicularly to the street axis about 9 in. Holes were drilled through steel forms to accommodate the tie bars which effectively tied curb, gutter and pavement together. An additional advantage lay in the fact that curb and gutter could be laid in advance of pavement. A more complete account of this feature of paving construction is contained in a recent issue of *Municipal and County Engineering*.

Abandoned Adit Used As Powder House.—An adit that was being driven to tap the tunnel on the Skagit project, now under construction to augment the water supply of Seattle, had to be abandoned, after advancing 160 ft. This was because of the formation encountered, which consisted of large boulders so loosely thrown together that a man could crawl through the air spaces between them ahead of the heading. After discovering that a strong cold draft came out of the abandoned adit all summer long and that it was free from dampness, a powder house was built in the adit entrance and has been found most satisfactory.

Controller Regulates Water Flow Through Pressure Filters

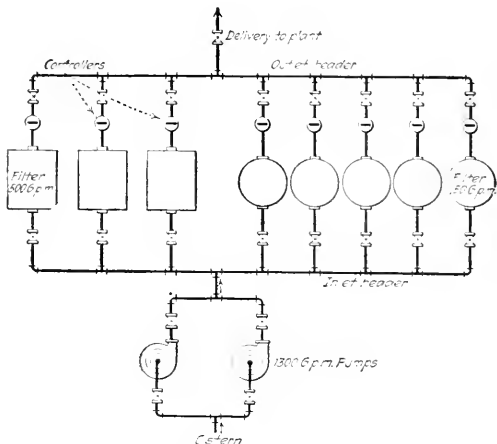

Device Reduces to Safe Capacity Water Passed Through Each of Eight Filters—Process of Filter Washing Also Improved

BY C. C. BROWN
Los Angeles, Calif.

A DEVICE for automatically regulating the flow of water through pressure filters was designed last year for use in a large Western industrial plant and has since been working very satisfactorily, entirely correcting the serious trouble that was the incentive for developing the device.

At the plant referred to there are five small and three large filters connected in multiple between an inlet and an outlet header, as shown in the accompanying plan. The inlet header is supplied with unfiltered water by two 1,300-g.p.m. centrifugal pumps and the outlet header delivers filtered water to the plant through a 12-in. line. The three large filters have an area of 160 sq.ft. of filtering surface and a capacity of 500 g.p.m., while the smaller units have an area of 50 sq.ft. of filtering surface and a capacity of 150 g.p.m.

The original installation had no provision for equalizing or pro-rating the flow through the individual filters and as the demand for filtered water was about equal to

ARRANGEMENT OF PUMP AND FILTER UNITS

their combined capacity, a large part of the flow passed through those filters that constituted the most direct route between inlet and outlet. This overburdened the units nearer the center and slighted those at the ends. Water was therefore forced through the centrally located filters at a rate greatly exceeding their normal capacity of 3 gal. per square foot of filtering surface per minute. Tests showed that some of the filters were operating at over 500 per cent rating and not only was the material in the filter beds disarranged, but sand was even driven out into the distribution system.

Another factor which undoubtedly made the trouble worse was the method of washing the filters. Washing was done by cutting a filter out of service, opening the

ELEVATION OF DEVICE FOR CONTROLLING FLOW

Control is effected by closing or opening of the butterfly valve by movement of rod attached to rubber diaphragm in middle of chamber, two parts of which are connected by pipes to trailing and leading sides, respectively, in the filter effluent.

waste valve, and turning filtered water through it in the reverse direction for a period of ten minutes. This wash water was taken from the filtered water line which was under a pressure of 100 lb. per square inch. The valve through which this washing water was admitted to the filters was "cracked open" only far enough to maintain a pressure on the filter side of 15 lb. per square inch. No doubt this method produced a jet action which tended to disarrange the graded material in the filter bed.

The problem, therefore, was two-fold: (1) to control the flow through the filters so that each unit would deliver at the maximum rate but could not be forced to a capacity beyond the safe limit, and (2) to provide means of safely and effectively washing the filters.

Automatic control of the flow was accomplished by the regulating device shown in the accompanying sketch. It consists of a counterbalanced butterfly valve operated by a rod attached to a rubber diaphragm. The diaphragm is in a chamber from the upper side of which a pipe leads to the trailing side of an orifice disc in the filter effluent pipe line. A pipe from the leading side of the disc taps the lower side of the diaphragm chamber. As the flow through the orifice increases above a predetermined rate, the diaphragm draws up the operating rod and moves the butterfly valve toward the closed position until the flow is cut down to normal. For a decrease in flow the reverse action takes place. This device is said to have successfully maintained the flow in all filters within 2 per cent of the desired quantity.

To provide means of washing the filters without danger of any jet action, a tank was installed at a height above the filter floor sufficient to produce a pressure of 15 lb. per square inch on a dead filter and of sufficient capacity to supply the flow of washing water desired for one filter for 10 minutes with the valve wide open. This storage tank was filled up slowly between washings, thus reducing the large washing demand, and the actual washing operation was not harmful to the filter beds nor did it tax the peak capacity of other filters.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Wants New Word for Concrete Aggregate

Sir—Several years I have urged the use of some other word instead of "aggregate" for the stone element in concrete mixtures. "Aggregate" in the dictionary is defined as "the whole"—not a part. Why not coin a word like "co-pards," meaning co-partners of cement and sand.

W. D. BROWNING,
Mechanical Engineer.

Memphis, Tenn.,
August 28, 1923.

Simplified Formulas for Eccentric Heel Joint of Truss

Sir—The formulas given by Camillo Weiss in the article "Trapezoidal Portal and Eccentric Heel Joints," in your issue of Aug. 30, p. 339, offer a satisfactory solution of a problem frequently occurring in practice and all too often neglected. For their further simplification, however, I would like to suggest the approximation $l_1/I_1 = l_2/I_2$ instead of $l_1 = l_2$. This makes $M_1 = M_2$, thus greatly simplifying the use of the equations in actual design. The results will not be as accurate in some cases, but considering other uncertainties any great accuracy is not warranted, nor is it necessary for design purposes.

Incidentally, I notice that in the article the expressions for M_1 and M_2 in the first two cases in which they occur are interchanged, by error.

WALTER H. WEISKOPF.

New York City,
Aug. 31, 1923.

Under Pressure and the Apishapa Earth Dam

Sir—I believe that the following line of reasoning has not been considered by hydraulic engineers and may account for some failures of dams and levees. The failure of the Apishapa earth dam, described in your issue of Aug. 30, p. 357, may or may not have been due to the thing I have in mind, but it is significant that the dam failed when the pool was not full nor even up to the load of the spillway; also that it leaked some time before the failure, and the leaks were stopped and the trouble apparently remedied.

When a leak occurs in the downstream face of an embankment, or on the land side of a levee, the most natural thing to do is to stop that leak by compacting the soil. It is just this process that has given rise to greater leaks and to failures. When the surface soil is compacted, the leaks may be stopped for a while, but a condition is set up by the compacting of the soil in a superficial way that is apt to create a greater menace than the loss of the water that may be trickling through the leak.

I refer to the thing that has caused the failure of so many masonry and concrete dams, namely, under pressure—the accumulation of a water head under a block of masonry or concrete that, with the horizontal pressure on the upstream face, lifts the block and either allows the water to flow under it and wash away the soil beneath or overturns the block, with the result that the dam fails. A large number of dams have failed from this cause, because they were not wide enough at the base to stand against the combined pressure.

The menace in the case of an earth dam is an accumulation of water pressure under a shell of compacted earth that is sufficient to lift it. Once lifted there is exposed a softened mass of soil to which the water has had access, and which that water has rendered semi-liquid. The exposure of this semi-liquid material, and its free vent, results in a leak of greater consequence than the one previously discovered and rolled or tamped to cause it to seal up.

Compacting or paying a surface where water with a head is apt to accumulate under the surface is fraught with great danger. Leaks discovered in such surfaces need special treatment. They should be dug out and the course of the water traced to its source, if possible. Or some sort of sub-soil compacting should be employed, something that will not produce an impenetrable shell for water to lift.

EDWARD GODFREY.

Pittsburgh, Pa., Sept. 1, 1923.

An Irregular Standard

Sir—In *Engineering News-Record*, Sept. 6, p. 372, "An Irregular Standard," 4th line from the bottom of the paragraph, reads: "one may be curious to know." If he wants to know very bad, he might look up "Life of George Stevenson," and find that the old coal pit tramways of about 100 years ago, for which George Stevenson built his first "locomotive engines," had 4 ft. 8½-in. gage; which thus came to be perpetuated; and isn't bad, as you say.

New York City,
Sept. 7, 1923.

CLEMENS HERSCHEL,
Civil and Hydraulic Engineer.

Measurements by Eighths of an Inch

Sir—Recently the plat of a survey in the vicinity of New Orleans was referred to me for interpretation. The sketch showed a front dimension, with notation as follows: 63.11.3', the lot being subdivided into two plots with dimensions as follows: 31.11.5' and 31.11.6', respectively. On first glance it would appear that the last digit represents thousandths of a foot. Another engineer was authority for the interpretation that the notations, in order, represent feet, inches and tenths of an inch. A summation of the dimensions however, bears out the writer's conclusion that the dimensions are noted as feet, inches and eighths of an inch.

Still more recently, a survey from the same locality, bears the dimension 52' 6" 7". Is the writer correct in interpreting this dimension, as before? Secondly, are these notations peculiar to certain localities, or are they merely characteristic of the individual engineers preparing the plats?

If there exist systems of notation in various parts of the country differing from the widely accepted standards, a summary of them might be of interest to engineers having to do with data from widely separated localities.

New Brunswick, N. J.
Aug. 12.

ERIC FLEMING,
Civil Engineer.

[The foregoing letter was sent to one of our southern correspondents who gives the following information.—EDITOR.]

Sir—In reply to your letter of August 28 enclosing letter from Eric Fleming, I would say that the dimension 31.11.5' and 31.11.6', as well as the dimension 52' 6" 7" would be interpreted in this vicinity as meaning, respectively, 31' 11½", 31' 11⅞", and 52' 6⅞". It is common experience to find dimensions given in this manner in the old notarial records.

It might be interesting to note that in a circular issued some time ago by Grandjean, Daney & Waddill, surveyors of New Orleans, the following explanation of surveying terms used in the South is made:

"The lands of Louisiana while a French colony were first surveyed by *arpents*. Spanish rule maintained this standard of measurement and our laws yet prescribe that plats of surveys shall indicate measurements in French as well as in American measure.

"The *arpent* is the old French lineal measure comprising 30 *toises* of 6 ft. each of the City of Paris. Its true equivalent in American measure varies according to different authorities from 191 ft. 93 in. to 191 ft. 103 in. but is considered as 192 ft., or 2909 chains by the U. S. Government."

This same circular contained a table giving French feet and their U. S. equivalents, the French foot being 1 ft. 0 in. and 6 *lines* (formerly *lignes*) long or 1 ft. and ⅙ of an inch.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

Contract for the Installation of 110 miles of automatic train control system between Camden and Atlantic City on the Philadelphia and Reading R.R. has been awarded to the Union Switch & Signal Co., of Swissvale, Pa. The first contract is for \$300,000 and the complete work will require \$500,000. It is believed that this is only the second case in which a whole division is to be equipped with automatic train control.

The Alaska Mineral Development Co. has applied to the Federal Power Commission for an extension of one year on its preliminary power permit in order to enable it to modify its plans to suit the requirements of the Bureau of Fisheries. The company, which is affiliated with the Guggenheim interests, had submitted plans for a power development on Bradford Canal in Alaska, but the original plan conflicted with the fishing interests.

The Pike Rapids Power Co. has received a license to construct a hydroelectric power plant on the Mississippi River near Royalton, Morrison County, Minn. A dam 42 ft. in height and a power house will be constructed just above the Minneapolis, St. Paul & Sault Ste. Marie R.R. bridge. The project will have an ultimate capacity of 24,000 hp. for use in pulp mills and iron industries.

The War Department Announces that there will be a public hearing held at the County Court House, New Brunswick, N. J., at 2 p.m. daylight saving time, Wednesday, Sept. 26, in the matter of the proposed New York Bay-Delaware River section of the intra-coastal waterway. All interested parties are expected to attend and for the purpose of accuracy of records persons having important facts and arguments to present are requested to submit them in writing. Maps showing the location of the proposed canal and the estimates are on file at Room 604 Army Building, New York City.

As a Result of the Dissension between the American and Canadian groups of the Ottoman-American Development Co., arbitrators have decided that Rear Admiral Colby M. Chester and his associates will withdraw from the development company upon payment by the company of \$300,000 within 90 days of the award. The Chester group will, however, retain a 10 per cent interest in the Ottoman-American Exploration Co., a subsidiary of the principal corporation. With the withdrawal of the Chester group from the development company, Col. K. E. Clayton-Kennedy, a Canadian engineer, will be the principal representative of the company in the field. Engineers of the company were due to sail for Turkey this week.

Anthracite Miners and Operators Agree on Contract

Agreement on the principles of a contract which is to run two years, and which grants to the miners a 10 per cent wage increase and the eight-hour day, provides for a thorough study of the industry and acknowledges the right of labor to bargain collectively, was made by anthracite operators and miners in a conference in Harrisburg, Sept. 8, as a result of a series of conferences called by Governor Pinchot, of Pennsylvania. The tentative contract was taken before the full scale committee of the United Mine Workers of America, which body ratified it. A tri-district convention is to be called Sept. 17, and upon ratification of the contract by that convention work in the hard coal fields is expected to resume within 48 hours.

Miners agreed at this time to drop insistence upon the check-off on union dues and the operators agreed to give up temporarily at least the demand for arbitration.

Statement of the miners is to the effect that the new contract, which will be in force until Aug. 31, 1925, is the best that the industry has ever seen, so far as they are concerned.

Samuel D. Warriner, spokesman for the operators, asserted after the conference that mine owners were relieved that a settlement had been made, but that he did not believe a wage increase was justified at this time. However, he added that it was not the desire of operators to take the "responsibility of a protracted suspension in the face of Governor Pinchot's proposal."

Philadelphia City Council Stops Arch Street Subway Work

By action of the Philadelphia City Council, funds for construction of the subway in Arch Street have been withdrawn. This action stops work under the contract awarded by the city on July 27 to the Keystone State Construction Co. for \$1,198,555. The action of City Council was taken following a message from the mayor pointing out that so long as the money was available he felt compelled to go ahead with the work.

The Arch Street subway was a portion of the "delivery loop" in the business section of the city, included in the transit plans voted upon in 1917. A few months ago the City Council withdrew the funds provided for the subway in Broad Street, and then mapped out new plans for comprehensive transit development in the city. The Arch Street subway is not included in the new plans, and the action of the Mayor under the conditions was very much criticized.

The present action of withdrawing funds after the contract has been awarded may make the city liable for damages for breach of contract, but no such action has been instituted.

Weeks Suggests Eliminating Gorgas Plant in Ford Bid

Detroit Manufacturer Confers With Secretary and Coolidge—Revised Offer Might Be Acceptable

Washington Correspondence

Henry Ford has taken under consideration a suggestion by Secretary of War Weeks that he amend his bid for a long-term lease of the Muscle Shoals hydro-electric project so as to eliminate from this offer acquisition of the Gorgas steam plant on the Warrior River.

Mr. Ford, accompanied by his son and engineers who have handled the negotiations for Muscle Shoals in his behalf, conferred Sept. 6 with Secretary Weeks and also with President Coolidge. Other than that the suggestion would be taken under consideration, there was no formal statement.

The Alabama Power Co., acting under the terms of the contract between it and the federal government when the Gorgas steam plant was extended by the government during the war, has notified the War Department formally that it desires the government to vacate this property and has offered to pay \$3,000,000 for that portion of the plant which was built by the government. According to informal statements of high officials of the administration, this price is considered fair.

AMENDMENT ONCE REJECTED

During the months of discussion in Congress regarding the disposition of Muscle Shoals, during which the Ford offer attracted outstanding attention, Mr. Ford declined on several occasions to amend his proposal so as to exclude the Gorgas plant. His desire evidently is to have an auxiliary steam plant where coal may be obtained the cheapest, and Gorgas is located at the mouth of mines on the Warrior River. It has been pointed out, however, that coal could be floated down the Tennessee River to an auxiliary plant at Muscle Shoals itself at low transportation cost.

From the fact that a conference on this subject was held with Mr. Ford at the request of government officials, it is generally believed in Washington that if Mr. Ford were to amend his offer so as to eliminate the Gorgas plant, the administration probably would throw its influence towards acceptance of his bid.

Gage Changing on Provincial Ry.

Changing the gage of the Prince Edward Island Railway from 3½ ft. to the standard gage of 4 ft. 8½ in. is progressing rapidly. It is being accomplished by laying a third rail outside the narrow gage rails to provide for the operation of both standard and narrow gage equipment over sections of track connecting subdivisions having different gages.

Dr. Karl Imhoff Visiting America

Dr. Ing. Karl Imhoff of Essen, Germany, well known for his work in connection with the two-story sewage settling and digestion tank that bears his name, arrived in New York on Sept. 9 for a two weeks' stay. He will visit a few sewage-works in the East and in Chicago and vicinity.

Morris Knowles Heads Pittsburgh Zoning Appeals Board

Morris Knowles, consulting engineer of Pittsburgh, has been made chairman of a three-member commission, to which may be appealed decisions of the superintendent of the Pittsburgh Bureau of Buildings in the matter of zoning law interpretations. The board is empowered to reverse or affirm, wholly or in part, any requirement or determination appealed from, in order to obtain conformity with the zoning ordinance.

The board also is given power to interpret the provisions of the ordinance in cases in which the street layout actually on the ground varies from the street layout shown on the zone maps, in such a way as to carry out the intent and purpose of the zone maps.

Mr. Knowles, who, as chairman of the board, will receive \$4,500 a year, is to serve until Jan. 1, 1924. The other two members will receive \$4,000 a year each.

North End Bridge in Springfield Destroyed by Fire

Special Correspondence

The North End Bridge, connecting the city of Springfield and West Springfield, Mass., and having an estimated replacement value of \$500,000, was completely destroyed by fire Sept. 8. It was built in 1878 and was of the Warren type, containing 5 spans, and the first steel highway bridge in the locality. The fire, which it is believed started from a burning cigarette, was given great impetus by the fact that floor joists were tar-coated timbers supporting creosoted wooden block paving. Burning gas from a broken main hastened the bridge's destruction. Within ten minutes three spans had been entirely destroyed and inside of an hour two of the remaining spans had fallen. Firefighters first drew water from a hydrant at a point where the pressure was so great as to burst hose lines. At another point the pressure was too low to be of great service. The falling of high-tension wires also made the firefighting difficult.

The bridge had been repaired and strengthened repeatedly. In 1909 some floorbeams were strengthened and reconstruction work was done on the two end spans. Three years ago a new floor was laid, some steel replaced by stronger members and \$25,000 was spent in general repair work by the Springfield Electric Railway Co. The maintenance of the bridge has been mainly borne by the city of Springfield and the town of West Springfield. The opening of the new Hampden County Memorial Bridge last year was designed to relieve the North End bridge of much traffic, but the general opinion prevails that a bridge on the site of the North End bridge is indispensable. An inquiry has been started into probable cost of a new structure. The City Planning Board advises a wider bridge be provided than the old.

Engineer Wins Capital Prize in Traffic Problem Contest

Arthur S. Tuttle, chief engineer of the Board of Estimate of New York City, won the first prize of \$1,000 offered by various national vaudeville circuit managers for the best suggestion for relief of New York City traffic congestion. The \$1,000 prize, together with one of \$300 and another of \$200, were offered in connection with the recent Silver Jubilee sponsored by Mayor Hylan.

Mr. Tuttle's proposals include relieving the section adjoining 42nd St. by making all north and south streets one-way streets and introducing the block system of traffic control; continuing Riverside Drive from 72nd St. to the Battery as an express highway or as an elevated structure with occasional ramps to the street; and arcing sidewalks so that the present entire width of congested streets be made available for vehicular traffic.

American Construction Council To Hold Annual Meeting

The annual meeting of the American Construction Council is to be held in the Engineering Societies Building, 29 West 39th St., Friday, Sept. 21. No details of the program are yet available, but it is certain that important matters confronting the construction industry with respect to labor supply and unemployment will be discussed. The Council is co-operating with local building congresses in investigating these problems as well as making a survey of apprenticeship needs.

D. Knickerbacker Boyd, Philadelphia, has been appointed to the recently created office of executive vice-president, and Dwight L. Hoopingarner, Cleveland, has been made executive secretary.

To Study the Power Resources of Pennsylvania

The State of Pennsylvania has organized a survey board to be known as the Giant Survey Board for the purpose of studying all the available sources of energy within the state and to outline the best methods of utilizing them. The survey will be in charge of Morris L. Cooke, formerly director of public safety in Philadelphia. Other members of the board include Attorney General Woodruff as vice-chairman, Major Robert Y. Stewart as secretary, W. D. B. Ainey, chairman of the Public Service Commission, George H. Ashley, state geologist and Robert H. Fernald, director of the Department of Mechanical Engineering at University of Pennsylvania.

The study will include the possibility of development of power at the mines and the economies to be effected through the recovery of the byproducts from the coal so used. It will also study the question of transmission with special reference to the requirements of small communities and farms, with the idea of putting these people on the same basis as city dwellers as far as power is concerned.

It is hoped that the cost of power will be materially reduced by the proposed large scale production through the reduction of transportation charges on coal and the elimination of waste.

Public Buildings Bill Again Before Administration

Congressional Committee Present Coolidge Views on Construction of Federal Buildings

Washington Correspondence

While the situation in the construction industry has eased according to reports to governmental agencies, in so far as over-ordering of materials is concerned, there is no change in sight sufficient to alter the attitude of the national administration toward a widespread program of construction of federal buildings.

Chairman Langley and Representative J. Will Taylor, of the House Public Buildings Committee, recently presented to President Coolidge the views of the majority of that committee that an omnibus public buildings bill with an appropriation of at least \$100,000,000 should be enacted early in the life of the next Congress. While admitting the need for more adequate facilities for federal departments in various cities, it is understood that the President indicated opposition to an omnibus bill under conditions which exist at present. This was the view also of the late President Harding, and it is the view of Secretary of Commerce Hoover and of Secretary of the Treasury Mellon.

PROPOSAL KILLED LAST SEASON

A proposal for an omnibus buildings bill was killed in the last Congress by opposition from the administration and the same fate appears to be awaiting any similar proposal in the incoming Congress, next Winter at least.

It is understood that President Coolidge agrees with Secretary Mellon who recently asserted that there is imperative need for several buildings in Washington to house branches of the various departments, some of which are now occupying wooden buildings erected as temporary structures during the war and which are rapidly falling to pieces. There is considerable doubt, however, that a building program for the federal government in Washington would be approved by Congress unless it went hand in hand with a considerable program of construction outside of Washington.

It may be possible to secure consent for the passage of a bill authorizing construction in Washington and in a number of other cities, but without carrying an appropriation for the work, actual construction to be held up as a pool for the stimulation of the industry when private contracts become slack. There are a number of conflicting ideas to be reconciled even in a plan of this character, however.

St. Louis Engineers Ask Voice in Expending Huge Sum

The St. Louis section of the American Society of Mechanical Engineers has recommended that an engineer be employed to serve the Citizens Supervisory Committee charged with the administration of the \$88,000,000 municipal bond issue recently voted by the City of St. Louis, Mo. The engineers point out that practically all of the work involved by the bond issue is composed of engineering problems, yet not a member of the Citizens Supervisory Committee is an engineer.

Work Forms Commission to Make Reclamation Study

Seven Prominent Men Including
One Engineer Invited To
Serve on Body

The formation of a fact-finding commission to investigate the whole system of Government methods in reclaiming arid and semi-arid lands by irrigation was announced Monday by Secretary of the Interior Work. Invitations were sent to seven citizens of national prominence asking them to serve as members of the commission and conduct an intensive study of the problem. They are: Julius Barnes, president, U. S. Chamber of Commerce; Oscar E. Bradfute, president, American Farm Bureau Federation; James R. Garfield, former Secretary of the Interior; Elwood Mead, consulting engineer and author of works on irrigation and reclamation, Berkeley, Calif.; former Governor Thomas E. Campbell of Arizona; former Governor David W. Davis of Idaho, Commissioner of Reclamation; and Dr. John A. Widtsoe, former president of State University and State Agricultural College of Utah.

TEXT OF INVITATION

The letter of invitation sent Monday by the Secretary of the Interior is as follows:

"The purpose of this letter is to invite you to serve with six other men having national confidence, on a fact-finding commission, to make an intensive study of the policy, application and operation of Government methods of reclaiming arid lands by irrigation, which has become a matter of national concern.

"It is generally reported that relatively few of the original settlers on projects now remain on them as water users. One hundred thirty-four millions of Government money have been expended. Fourteen millions have been returned and six millions are due and unpaid as of Dec. 31, 1922 to which must, very soon, be added computations for the present calendar year.

"Time extensions for payment of both construction and maintenance charges have been asked which, if granted, would multiply deferred annual payments, it is feared, beyond the ultimate ability of the settler to pay, entailing probable loss of his home and to the Government the loss of the investment.

"The purpose of this inquiry, in which I very much hope you may participate, is to have the processes of administration of this trust reviewed by men of affairs applying their best thought to this important governmental agency.

"Reclamation has done much toward the development of the west, but it now clearly requires to be adapted to existing conditions, so that its future success may be achieved and the possibility of home ownership be assured to settlers.

"Your commission will, of course, be provided with suitable offices, necessary data and the courteous assistance of the Bureau of Reclamation.

"As the work progresses, you will be supplied with itemized statements and complaints coming in, of which I must take cognizance, and which may serve to indicate the direction the commission may be prompted to take in its inquiries.

"Although only recently charged with

California Allots \$10,000 Toward San Pablo Dam Survey Fund

The United States Reclamation Service has made an allotment of \$20,000 toward the surveys of the proposed dam across the lower end of San Pablo Bay, which is an arm of San Francisco Bay, and related work, contingent upon an equal amount being provided from other sources. On Aug. 31 W. F. McClure, state engineer of California, announced that \$10,000 will be contributed by the state toward this work. It therefore remains for a committee recently created by the Sacramento Valley Development Association to secure the remaining \$10,000.

The proposed dam is expected (1) to solve the salt water problem in the lower reaches of the Sacramento River; (2) to afford a large fresh water harbor free from tidal effects; and (3) to provide a highway route across the bay at this point.

Uniformed Crossing Watchmen Command Respect

Due to the flagrant disregard of the warning of crossing watchmen at Youngstown, Ohio, the Erie Railroad Co. has had its crossing watchman appointed as a regular member of the police force of the city and properly uniformed as such. Under this new arrangement he has been able to demand the respect of automobile drivers on the highway the same as any traffic policeman with the result that there have been no more accidents due to disregard of his orders, nor have the crossing gates been broken as they occasionally were previously. The plan has been so successful that other railroad companies are now considering it for use in similar locations.

Detroit Engineering Society Acquires New Home

In early October the Detroit Engineering Society will hold a house warming in a clubhouse which has but recently been acquired. Alterations are now being made on the house, which is a large residence located at 478 Alexander Ave., West. Acquisition of the property is the result of a plan definitely outlined a year ago providing for the purchase and equipping of a house for about \$65,000, and the incorporation of the society. The society was incorporated in early June of this year.

In order to care for increased service which the society will offer in its permanent and enlarged quarters E. L. Brandt has been engaged as managing director. Mr. Brandt is a civil engineering graduate of the university of Michigan and spent one year with the American Bridge Co., 15 years with the Michigan Central R.R. at Detroit and a year as assistant secretary of the American Association of Engineers at national headquarters.

the responsibility of reclamation, I am not a stranger to the irrigation of arid lands, but prefer, however, not to suggest procedure and would not expect to advance opinions to this commission unless requested, asking only that the questions may be treated with open publicity and that I may transmit your report to Congress."

\$175,000 More Asked for Lake Worth Bridge

A bridge across Lake Worth, to connect Palm Beach and West Palm Beach, originally estimated to cost \$200,000 will cost \$450,000, engineers have reported to the board of county commissioners. The county commissioners have authorized a call for bids for the purchase of \$175,000 worth of bonds to provide the remainder of the money needed to complete the bridge.

An eastern engineering firm made soundings of the formation under the lake and estimated the base rock as not thick enough to support the bridge. The rock broke under the weight of piers and sections of the bridge that collapsed eighteen months ago. More complete data as to the foundation caused engineers to agree that many piles would have to be driven; this course was adopted and was one of the reasons why a larger cost will be necessary.

The legislature had authorized the county commissioners to issue the \$175,000 additional bonds for which bids will be asked.

C.P. Ry. Completes Two Surveys Across Rocky Mountains

Montreal Correspondence

Four Canadian Pacific Ry. survey parties which have been working in the Rocky Mountains during the past season have, according to press despatches, about completed their work and are now preparing their reports.

It is understood that these parties have been studying two possible routes across the Canadian Rockies with the idea of extending the Edmonton, Dunvegan and British Columbia Ry. from its present terminus at Spirit River in the Peace River country in Alberta to some point on the Pacific Coast.

One of these proposed routes runs due west from Spirit River across British Columbia to a point on the Portland Canal north of Prince Rupert. The second route goes west from Spirit River to Pine Pass in the Rockies and then due south along the Parsnip River to Prince George on the Grand Trunk Pacific and thence south down the Fraser River to connect with the Pacific Great Eastern Ry. at Quessal, a distance of 380 miles, with a possible 55-mile connection between the southern end of the Pacific Great Eastern and the C.P.R. near Vancouver.

The construction of either line would be a great engineering feat and the proposal is interesting from that point of view but from the point of view of present practicability either seems unnecessary and it is doubtful whether the C.P.R. is seriously considering any such undertaking. There are at present three transcontinental railways across British Columbia which give the greater part of the prairie provinces access to the Pacific ports. The only section that is not so served is the Peace River country, but it is a new country which could not support a railway to the coast. For the present its traffic can be handled eastward through Edmonton. In the future when the traffic offered is greater than the present routes can handle then some such new route to the Pacific will be of real practical interest.

Employment of Engineers Active in Central States

Salaries on West Coast Lower Than Elsewhere—Pay Averages Given for Various Services

Employment conditions affecting engineers are most active in the central and southern states, particularly in the highway, railroad, municipal and building fields, according to the employment service of the American Association of Engineers. In the East and Northeast, conditions are not quite as active but there is a healthy demand for technical services around New York, Boston and Philadelphia, although Boston in comparison is dull. Engineering employment in the western states is sufficiently active to take care of practically all engineers residing in that section of the country.

ENGINEERS IN WEST

The West Coast and Southern California seem to be the mecca for a large number of engineers. High grade men are working for beginners' salaries either because they want to be there or are forced there on account of illness in their families. The A.A.E. Chapter secretaries in California have an oversupply of applications on hand for all classes of positions. However, a fair demand exists for electrical, telephone and architectural engineers but it is rather dull for the structural, concrete, municipal, highway or general construction engineers. Engineers wishing to enjoy the healthful climate of Southern California must, in a measure, be content with a lower salary than secured elsewhere. Practically no assistance can be given eastern men to locate positions in that district unless they go out there to be on the ground when a vacancy occurs.

AVERAGE OF SALARIES

From the best information available from a wide variety of sources covering the entire country, the average engineering salaries per month at the present time are as follows: Tracers, \$125 to \$150; detailers, structural, mechanical, and electrical, \$150 to \$215 (a few companies have paid for special short time jobs as high as \$250 a month for experienced detailers); designers on all classes of work, \$225 to \$300, with a few engagements at \$325 and \$350 where the men were able to take care of squads; estimators, \$300 to \$350; rodmen and levelmen, \$125 to \$160 (this includes highways, the municipal field and railroads); instrument men, \$150 to \$175 (where some responsibility was required such as chief of parties, \$175 to \$240); assistant engineers, \$225 or more depending on responsibility or class of work; map draftsmen, \$150 to \$200; surveyors, \$160 to \$190; research engineers, \$175 to \$250; construction engineers, \$200 to \$325; superintendents of construction, \$275 to \$500; resident engineers, \$200 to \$300 depending on class of work; industrial engineers, \$200 to \$500.

Salaries for engineers such as building superintendents and mechanical engineers vary with duties and company. For temporary positions, the average is about 20 per cent more than the figures given which are on permanent appointments.

Philadelphia Engineers to Confer on Stream Pollution

A conference will be held at the Engineers' Club of Philadelphia on Oct. 16, afternoon and evening, at which time pollution of streams, especially with reference to pollution by industrial waste, will be the chief topic of discussion. Representatives from the national, state and city governments, and several of the industries most interested in the subject will be present. Papers will be read and discussed by a number of engineers who are recognized authorities and are thoroughly conversant with the subject.

The complete program with the titles of papers and names of speakers will be ready before Oct. 1, and will be sent, together with an invitation to attend the meeting, to any engineers or industrial executives who may desire to be present and take part in the discussion.

Gen. Marshall Elected Head of Quartermasters' Association

Election of R. C. Marshall, Jr., of Washington, as president of the National Quartermaster's Association at the recent meeting in New York is expected to bridge the breach in the membership which was threatening the success of the organization as to whether control should be vested in the regular army officers or in the civilian group.

Gen. Marshall was induced to enter the contest only after being urged to become a compromise candidate. While he is now a civilian, holding the rank of brigadier general in the Reserve Corps and being a member of the contracting firm of Marshall and Maddox Co., Washington, and general manager of the Associated General Contractors of America, for many years Gen. Marshall was an officer in the regular army and served as head of the construction division of the Quartermaster Department during the war.

Gen. Marshall defeated Major Gen. William H. Hart, Quartermaster General of the Army, who was proposed for re-election.

Grand Canyon Survey Reaches Bright Angel Trail

The U. S. Geological Survey party making a trip through the Grand Canyon of the Colorado in boats has arrived safely at Bright Angel trail, Grand Canyon National Park, having traveled 90 miles without serious accident. This party, which consists of ten men headed by Col. C. H. Birdseye, started on Aug. 1 in four specially constructed lifeboats from Lees Ferry, Arizona, to complete a topographic survey of the Grand Canyon as far as Boulder Creek, Arizona, a distance of 310 miles.

The party is provided with a radio receiving set built especially for use in the Grand Canyon, and notwithstanding the predictions of radio experts that it would be impossible to receive radio messages while traveling in the bottom of Grand Canyon, Col. Birdseye reports that he is in daily receipt of messages broadcasted from Los Angeles, Salt Lake, and Chicago.

The party expects to complete its work early in November, but will send out reports of the progress made on reaching Basstrail about Sept. 10, Supai Creek Sept. 20, and Diamond Creek, Oct. 15.

Engineering Societies

Calendar

Annual Meetings

- NEW ENGLAND WATER WORKS ASSOCIATION, Boston, Mass.; Annual Convention, Burlington, Vt., Sept. 18-21, 1923.
- INTERNATIONAL ASSOCIATION OF STREET SANITATION OFFICIALS, Chicago, Ill.; Annual Conference, Chicago, Sept. 27-28, 1923.
- AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 8-11.
- AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 17-20.
- AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga., Nov. 12-16.
- CITY MANAGERS' ASSOCIATION, Lawrence, Kansas; Annual Meeting, Washington, D. C., Nov. 13-15.

The Iowa Section, American Water Works Association, will meet Oct. 24, 25 and 26 at Iowa State College, Ames. Preceding the meeting of the waterworks section the fifth conference of sewage operators in Iowa will be held Oct. 22 and 23.

Personal Notes

GEORGE H. FREDERICK, for thirteen years connected with the Department of Public Safety of St. Louis, Mo., and formerly chief inspector of building, resigned Aug. 31. His successor has not been appointed. Mr. Frederick will be associated with Edward M. David, house movers, St. Louis.

A. M. BARTON, Sacramento, Calif., has been promoted from assistant engineer of the California State Reclamation Board to chief engineer of the board, succeeding Peter R. Gadd.

C. E. FOSS, chief engineer of the New Brunswick Power Commission, and for many years an engineer on the construction of the Canadian National Railways, Transcontinental and Valley branches, has resigned and will live in New Hampshire.

J. G. GWYN, for a number of years chief engineer of the Denver and Rio Grande R.R., has been retired under the pension provisions of the road. He is succeeded by A. O. RIDGWAY, his assistant, and chairman of the safety committee. Mr. Ridgway has been with the Denver and Rio Grande continuously since 1908, serving a year as acting engineer of bridges and buildings, then becoming assistant chief engineer. Previous to 1908 he served other Western roads in an engineering capacity, though shortly after his graduation from the University of Kansas he joined the Denver and Rio Grande engineering forces, acting first as instrument-man, then as assistant division engineer and later as acting division engineer.

C. S. MACALLA, recently vice-president and general manager of the Virginian Power Co., Charleston, W. Va., and vice-president of the Coalburg Col-

liery Co., Ronda, W. Va., has been made vice-president and general manager of the Penn-Ohio Power & Light Co., Youngstown, Ohio. Mr. Macalla is a graduate of Lehigh University and for several years was connected with the General Electric Co. for whom he organized a new factory in Rochester, N. Y., and with the Washington Power Co., Spokane, Wash., where he was for five years vice-president and general manager.

J. C. McLeod, division engineer of the Oregon state highway department, and C. H. Whitmore, market road engineer of Oregon, have resigned to accept positions in the state highway department of California. Mr. McLeod will have his headquarters in Sacramento, and Mr. Whitmore has been assigned to San Francisco.

J. S. SAWYER, resident engineer at Springfield, Ore., for the Oregon State Highway Department, has been appointed a division engineer, succeeding J. C. McLeod, resigned; and J. H. Scott has been appointed engineer in charge of market roads in Oregon, succeeding C. H. Whitmore, resigned.

DORR Co., engineers, New York City, announce the removal of their Scranton, Pa., office to the Miners Bank Bldg., Wilkes-Barre, Pa., the better to serve the anthracite field. JOHN GRIFEN will still be in charge of this branch of the company.

CAPT. C. W. LOWMAN, of Carman, Man., who since 1919 has been on the engineering staff of the Manitoba government in charge of road improvement work, has gone to Colombia, South America, to take charge of railroad engineering for the Tropical Oil Co.

M. H. FERGUSON, of Toronto, has been appointed resident engineer of Port Hope, Ont.

CHARLES D. VAIL, railway and hydraulic engineer for the Colorado state public utilities commission, Denver, Colo., has been appointed manager of parks and safety for the city of Denver. Mr. Vail is a graduate of the University of Illinois; worked for the Union Pacific Ry. and Oregon Short Line Ry. on surveys, shop construction, division control and railway construction; and later served as assistant engineer of the city water department of Butte, Mont.

Obituary

JULIUS PITZMAN, pioneer of subdivision planning in St. Louis, Mo., died in that city Aug. 31 at the age of 86 years. Having at 16 years of age come to America from Germany, Mr. Pitzman studied civil engineering under his uncle and as early as 1857 he was chief of the county surveyor's office at St. Louis. He served in the Civil War in the Union army, as first lieutenant of engineers and later on General Sherman's staff as captain of engineers, and was wounded at the first siege of Vicksburg. After the war he returned to his post as county surveyor at St. Louis. He laid out Forest Park, Carondelet Park and O'Fallon Park for St. Louis, and also prepared plans for many subdivisions of the city. He was president of the Pitzman Company of Surveyors and Engineers.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

To Curb Profiteering in Lumber for Japan

Manufacturers Oppose Granting of Five-Daily Options to Exporters—
3,750,000,000 Ft. Needed

Steps are being taken by the Pacific Coast lumbermen, the National Association of Lumber Manufacturers announced today, to prevent the distress of the Japanese people being exploited by speculators. Through R. F. Hammett, secretary-manager of the California Redwood Association, the directors of the Douglas Fir Exploitation & Export Co., an exporting company of Pacific coast sawmill companies, wired the National Association as follows:

"We believe that inasmuch as a number of exporters are working for five-day options on large amount of lumber for Orient we should not put it in power of speculators to hold up the unfortunate people of Japan but should co-operate with those who are raising funds to relieve their sufferings. We have still approximately 40,000,000 ft. for Japan and it is unanimous opinion of meeting that we should grant no options nor accept any business until we know more about the situation."

In this connection the Red Cross national headquarters at Washington, D. C., authorizes the statement that it is acquiring for immediate shipment 9,000,000 ft. of lumber, half at Portland and half at Seattle, and that 6,000,000 ft. of this amount has been donated by two lumber companies. While there are reports of inquiries from Japan for large quantities for purchase, the Red Cross is not involved.

REQUIREMENTS ESTIMATED

The West Coast Lumbermen's Association, of Seattle, has wired the National Association that it is estimated that the rebuilding of the wrecked portion of Japan will call for the enormous amount of 3,750,000,000 ft. of lumber. This is more than all the mills of Japan could produce in a year and a half, but is not much more than a normal month's output of American sawmills. The 40,000,000 ft. referred to in the above dispatch represents unfilled Japanese lumber orders with the mills of the export company at the time of the disaster, the ordinary lumber exports from the United States to Japan being in large volume.

Outside of British Columbia the United States is the only available source of supply for Japanese lumber requirements. The sudden addition of 3,750,000,000 ft. to the current demand, especially if accompanied by the granting of options to speculators, might result in the absence of precautions that are being taken in the establishment of excessive prices for the lumber needed by Japan at this time. It is believed that the mills will concentrate on filling pending Japanese orders and also those arising from the emergency, deferring as much as possible a portion of the domestic and other export business.

Use of Steel Reinforcement for Concrete Roads Increases

The use of steel in the building of concrete highways in the United States has made rapid strides during the last few years. Expenditures for reinforcing material are now running into several millions of dollars annually, while in addition much of the equipment used in road building is also made of steel, adding considerable to the benefits derived by steel manufacturing companies as a result of the modern methods of highway construction.

Practically every state is now using steel reinforcing materials for the building of roads, with several, including Pennsylvania and California, using it to a greater extent than others. Data compiled by the U. S. Bureau of Public Roads shows that in 1921, the latest year for which official figures are obtainable, for 1,350 federal-aid projects involving 7,480 miles of road at a total cost of \$112,325,302, reinforcing steel for bridges and road slabs was used at a cost of \$2,375,966. This shows that the cost of the reinforcing material was 2.1 per cent of the total cost of the road.

This amount was divided as follows: Structural steel, \$976,571; expanded metal, \$50,619, and reinforcing rods, \$1,348,806. The figures have not been subdivided to show the percentage of material going into structures and road surface. Also, much steel is being consumed in the erection of metal signs, sometimes mounted on steel pipe or angle rods, which are replacing the wooden sign on the nation's highways.

Motor Vehicle Production

Demand for motor vehicles is holding up well, as indicated by production totaling 348,733 cars and trucks, as reported to the directors meeting of the National Automobile Chamber of Commerce held in New York Sept. 6.

Surveys indicate that fall prospects for both cars and trucks are better than last year. In Georgia, Illinois, Michigan, Nebraska, and parts of the Northwest August business was reported as better than July, though in the majority of the states the demand was reported as slightly less.

The increased production was 6.7 per cent over July and 28 per cent in excess of August, 1922. Last year the August increase over the preceding month was 10.8 per cent. The previous high August record was 272,744 cars and trucks in 1922.

The monthly output of motor vehicles for 1923 as compared with 1922 is as follows:

MOTOR VEHICLE PRODUCTION 1922-23

	1922	1923
January.....	91,109	243,104
February.....	122,366	276,467
March.....	172,728	354,319
April.....	219,358	382,001
May.....	256,219	393,193
June.....	289,011	377,759
July.....	246,607	327,102
August.....	272,589	348,733

* Estimated from carload shipment reports.

Simplified Practice Conferences To Be Held

A final conference of clay products manufacturers, distributors and consumers, looking towards an elimination of excess sizes and varieties, will be held with the Division of Simplified Practices of the Department of Commerce, Oct. 22. On Oct. 19 a final conference of hollow-tile interests will be held, while on Sept. 26, the final conference of the Prepared Roofing Association and allied interests is scheduled. A preliminary conference of garden hose producers and distributors will be held Sept. 14.

Equipment Dealer's Staff Safe in Japan's Earthquake

The Allied Machinery Co. of America, New York City, has received advice by cable from T. G. Nee, president of the Horne Co., Ltd., of Japan, that the entire head office staff of the organization in Tokyo is safe. The exact status of the merchandise stocks and of the records of the business in Tokyo has not yet been determined. Less than one-third of the company's stock is carried in Tokyo. None of the thirteen branches of the company in Japanese territory was affected by the recent disaster. The Horne Co., Ltd., is, therefore prepared to continue its business of nearly twenty-five years standing as distributor in Japan of American manufacturers of machine tools, industrial and construction machinery, building materials and allied lines. The Allied Machinery Co. of America, with which the Horne Co., Ltd., is affiliated, will continue to handle the affairs of the latter in this country.

Construction Equipment Exported

Domestic exports of construction equipment during June have been announced by the Department of Commerce as follows: 23 power shovels valued at \$83,490; 12 cranes at \$14,198; 394 hoists and derricks (except mining) at \$63,450; 61 concrete mixers at \$46,728; 504,329 lb. of "other road-making equipment" at \$64,245; 1,186,390 lb. of miscellaneous construction equipment at \$87,954; 27 conveyors at \$13,351; 192 centrifugal pumps at \$49,455; 599 steam pumps at \$109,711; 2,358 "other power pumps" at \$176,179; and 727,019 lb. of "other pumps and pumping machinery" at \$246,962.

Three of the power shovels, at \$18,553, went to Canada, one at \$12,130 to Peru, one at \$10,110 to Cuba.

Road Show Exhibitors Meet

A meeting of the Board of Directors of the Highway Industries Exhibitors Association was held Sept. 7 at the office of President S. F. Beatty, Austin Western Road Machinery Co., Chicago. Charles M. Upham, state highway engineer of North Carolina, recently appointed manager of the road convention and show, was present at the directors' meeting to discuss with the representatives of equipment and material manufacturers plans for the exhibit in the Coliseum, Chicago, next January, to be held during the annual meeting of the American Road Builders Association.

To Pave Around British Cenotaph with Rubber Blocks

Noise of London traffic at the cenotaph, Britain's war memorial at Whitehall, has led to special means for insuring silence at the spot to which thousands from all parts of the Empire make a pilgrimage. The surrounding area is to be laid with rubber pavement, the cost of the blocks, estimated at \$30,000 being paid for as a gift to the country by Rubber Roadways, Ltd. The superficial area of the strip to be paved with rubber is 1,500 sq.yd., stretching right across the Whitehall carriageway and extending half way to Downing St. on the Westminster side and an equal distance towards Charing Cross. Each block weighs nearly 5 lb. and measures 8x4x3 inches.

Japanese Restoration

Washington Correspondence

While the earthquake disaster in Japan undoubtedly will bring an increase of orders to American firms for building materials, it is not believed by those familiar with Far Eastern affairs that there will be any tremendous flow of such orders. This prediction is based upon the fact that most of the buildings in the devastated area were constructed of wood and in all probability will be replaced by wooden structures. Some slight increase in orders for structural steel may be looked for, it is believed, but not in sufficient volume to affect to any great extent the market for these commodities.

Under the conditions with which Japan will attack reconstruction of the destroyed areas of her Empire, with many of her subjects thrown out of normal employment and hence available for labor, one economist has pointed out that in all probability reconstruction can be accomplished at much less cost than if the same amount of building were to be done piecemeal and under normal conditions.

Contractors Urged to Select Standard Equipment

The Associated General Contractors of America is urging its members to choose their construction equipment in accordance with the recent standards for concrete mixers and wheelbarrows approved by the Joint Committee on Construction Equipment, which has held several meetings recently in Chicago and Detroit.

Manufacturers are given until 1925 to dispose of the non-standard equipment they now have in stock. The bringing of standard equipment into general use, it is pointed out, will have been accomplished long before the end of the coming year. Equipment of the standard type approved will carry name plates showing authorization by the Associated General Contractors and eventually none but mixers and wheelbarrows of the standard type will be available on the market. Name plates to be placed on equipment conforming to the recently announced standards soon will be available to manufacturers.

It is suggested by the contractors' organization that the elimination of unnecessary types or sizes of equipment will reduce the manufacturing overhead and consequently should be reflected in equipment prices.

American Machinery Gains Favor in Japan

Notable Changes in British and American Positions Shown by Commerce Department Figures

AMERICAN machinery manufacturers interested in obtaining a broad view of happenings in their respective lines in Japan will find useful figures compiled recently by the U. S. Department of Commerce, and taken from the Japanese customs statistics. A graphic analysis of these figures by the Industrial Machinery Division of the Department shows the comparatively insignificant part played in this business by the United States in the earlier years; the phenomenal growth of American participation in certain lines with corresponding waning of the British volume; and the subsequent regaining of lost ground by the British in some cases. In many lines the American manufacturers are holding their own and even increasing their hold, though the British have regained their former prestige, to a large extent in those lines where the original machinery installed was British and the repairs and replacements were of necessity British.

In the earlier years the British controlled the market but in the first part of 1915, owing probably to the war demands on British manufacturers, their participation in this business fell to a negligible quantity, while the American participation took a sharp upward trend. The point of especial interest, the Commerce Department states, is that in the post-war years the British have been unable to regain their former supremacy.

In 1913 the dominant position in the imports of each class of machinery into Japan was as follows:

British	American
Steam engines, boilers, and fuel economizers;	Knitting machinery.
Steam and water turbines;	Gas compressors.
Gas, petroleum and hot air engines;	Blowing machines.
Pumping machinery;	All other machinery.
Cranes;	
Metal or woodworking machinery;	
Paper making machinery;	
Power hammers;	
Spinning, weaving, and tissue finishing machinery;	
Capstans, etc.;	
Hydraulic presses;	
Blocks and chain blocks;	

This comparison shows clearly that the British held the control in the majority of items, their percentage to the total being 48.4, as against the American percentage of 8.7. By 1920 the situation had altered until the British percentage was only 20.6, compared with the increased American percentage of 51.4, and the specific classes of machinery were as follows:

British	American
Steam engines;	Steam turbines and boilers;
Gas, petroleum, and hot air engines;	Water turbines;
Spinning, weaving, and tissue finishing machinery;	Pumping machinery;
Fuel economizers.	Metal or woodworking machinery;
	Paper making machinery;
	Knitting machinery;
	Capstans, etc.;
	Gas compressors;
	Blowing machines;
	Hydraulic presses;
	Pneumatic tools;
	"All other machinery."

Business Notes

GRAVER CORP., East Chicago, Ind., manufacturers of water softeners, filters, tanks and general steel plate construction, announces the following changes in its district sales offices: The office formerly located at Los Angeles has been discontinued and the Water Works Supply Co., 536 Call Building, San Francisco, will represent the company in the State of California. The Seattle office has been discontinued and the States of Washington and Oregon will be in charge of H. K. Mead, 409 Board of Trade Building, Portland, Ore. The Philadelphia office has been discontinued and L. C. Holmes, 918 Buchanan St., N.W., Washington, D. C., will have charge of sales in that district.

GEORGE A. MCCLELLAN, recently county engineer of Harrison County and stationed at Marshall, Texas, and previous to that state division highway engineer, is now district engineer for the asphalt sales department of the Texas Co. He is located at Dallas. O. F. REYNAUD has been appointed district engineer of the asphalt sales department of the Texas Co. at Houston. Mr. Reynaud is a civil engineering graduate of Texas A & M College.

Equipment and Materials

Trailer Mounting for Mixer

To relieve contractors of the necessity of loading a concrete mixer onto a motor truck when moving from one job to another the Marsh-Capron Co., Chicago, has developed a trailer mounting for its 1-bag Universal mixer which can be towed behind a truck traveling at 25 to 30 miles per hour. The rear axle is equipped with large springs to reduce vibration. As shown in the accompanying illustration the front end

of the trailer is equipped with a double-wheeled swivel castor which is raised clear of the ground during towing and rests on the ground when the mixer is in service so that the outfit may be moved about as readily as with a four-wheel mounting.

The steel disk wheels have $3\frac{1}{2}$ x 24-in. solid rubber tires, and turn on 5-in. Timken bearings on a 1½-in. heat-treated automobile axle. The springs are of the best automobile truck design, silicon manganese steel, 9 leaves 1-in. thick by 2-in. wide, 32 in. long overall. The front castor has two roller type wheels, each

3½ in. face by 15 in. diameter; the castor wheels are carried in a heavy cast steel fork, with the pivot pin integral. The triangular tongue is built up of $3\frac{1}{2}$ x $2\frac{1}{2}$ x ½-in. angles, with 2½ x ½-in. braces. It has a heavy steel clevis riveted to the end, for attaching to trucks, and hand grips besides.

Reflecting Hand Level

A reflecting hand level, intended primarily for use on surveys of roads and railways, but adapted also to the same purposes as any clinometer where the slopes are not greater than 11 deg. 15 min. above or below the horizontal, has been developed by the Keuffel & Esser Co., New York.

Its essential parts are a movable

arm carrying a bubble tube, a graduated limb and a prismoid reflector. It is named the Fallis reflecting hand level.

The bubble tube is large and has adjustment devices similar to those on the bubble tubes of a surveyor's transit. The graduated limb is set perpendicular to the line of sight and is graduated in per cent of grade up to 20 per cent above and below the horizontal. The length of the limb permits direct graduation to single per cents, and the spaces being large, it is possible to estimate to the nearest 0.2 per cent.

The movable arm, which carries the bubble and pointer, is operated by means of a tangent screw, whose head is at the base of the graduated limb. Hence, the bubble may be brought slowly and uniformly to the center of its tube, instead of, as in the Abney level, requiring a direct operation of the hand in positioning and clamping

Publications from the Construction Industry

Formwork for Flat Slabs—BLAW-KNOX CO., Pittsburgh, in a 20-p. bulletin, describes and illustrates its metal forms for flat-slab concrete construction, including details of shoring, panels, columns and walls, and outlines the advantages of the use of metal forms. The Blaw-Knox service in the use of these forms includes a rental price on steel forms, erection schedules and a service man to aid in installation and quotations on forms erected in any part of the country.

Asphalt Joint Fillers—MIN-WAX CO., INC., New York City, has issued a 4-p. illustrated pamphlet on its asphalt joint fillers and calking compounds, including cements for expansion joints of various kinds, calking rope and fillers for grooves and cracks. Points to be followed to secure successful use are also outlined. Drawings illustrate the use of the product in such typical cases as sidewalk expansion joints, bridge expansion joints, block paving joints, spandrel wall expansion joints, and flushing grooves at curbs.

Rail Welding—METAL & THERMIT CORP., New York, has issued a 72-p. illustrated booklet bringing up to date the subject of thermit rail welding. Detail instructions are given for making improved rail welds. For this purpose apparatus has been developed including the self-luting mold box and a new lightweight double burner preheater. Results of rail bending and drop tests are given. The pamphlet concludes with a discussion of the theory of rail joints.

Rock Crushers—UNITED IRON WORKS, INC., Kansas City, Mo., features its portable and stationary rock crushers in a recently published bulletin. The capacities range from 6 to 35 tons of material per hour. The crushers are of the jaw type, requiring for operation from 6 to 20 hp. Several illustrations show the crusher at work on road construction, together with auxiliary plant in the form of bucket elevators, screens and bins.

Pine Floors—SOUTHERN PINE ASSOCIATION, New Orleans, is distributing a 16-p. illustrated booklet containing detailed directions for the laying, finishing and care of Southern pine floors in commercial buildings, private homes, theaters, banks, schools, armories, and factories. The booklet is entitled "Beauty Plus Service in Floors."

Steel Wheels—GENEVA METAL WHEEL CO., Geneva, Ohio, features its steel wheels for all kinds of portable outfits, except automobiles, in a newly issued 29-p. illustrated booklet. The wheels are of both light and heavy design for construction equipment such as wheelbarrows, concrete mixers, crushers, tractors and trailers, portable pumping plants, wagon loaders, etc. The wheels are constructed in a variety of diameters and tire widths.

it. The location of the limb and tangent screw at the sighting end of the instrument permits the use of both hands in directing it steadily upon the mark while bringing the bubble to the central position.

All of these features, the manufacturers claim, make possible a considerable degree of precision in measuring slopes and gradients up to 20 ft. rise in 100 ft. of horizontal distance. The instrument is equipped with a narrow prismoid reflector, so located that the field of view appears on both sides of the reflected bubble.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Production and Materials Stocks in Nine Cities

Iron Output Lower—Production of Other Materials Increased— Unfilled Steel Bookings Dropped 496,100 Tons

Iron and Steel—August pig-iron output totaled 3,435,000 tons as against 3,678,000, for the month preceding, a decrease of over 6 per cent.

Steel ingot production, however, reached 3,508,347 tons during August, compared with 3,350,829 for the preceding month, a gain of nearly 5 per cent. Compared with one year ago, the August steel output gained over 54 per cent according to the American Iron and Steel Institute.

Unfilled steel tonnage, on books of the U. S. Steel Corp., Aug. 31, totaled 5,414,663 tons, compared with 5,910,763, July 31 and 7,403,332 on Mar. 31, 1923.

Lumber—Production is proceeding at about 10 per cent above normal as against 7½ per cent, one month ago. Shipments are a trifle under, and orders slightly over, 100 per cent of normal production, according to the National Lumber Manufacturers' Association. Production, shipments and demand, all increased materially during August. One year ago, however, production just touched normal, with shipments nearly 90 per cent and orders, 92½ per cent of normal production. The following table shows lumber movements during the four weeks ending Aug. 25, compared with the preceding four weeks:

	Four Weeks Ending—	
	Aug. 25 P.T. b.m.	July 28 P.T. b.m.
Cut	1,995,378,957	1,010,866,675
Shipments	936,731,282	887,213,878
Orders	879,631,526	808,465,374

Cement—Reserve stocks, throughout the entire country Aug. 1, totaled 8,076,000 bbl. as against 8,433,000, for the corresponding period in 1922, according to the Geological Survey. Production, however, totaled 74,940,000 bbl. for the first seven months of the current year as against 58,475,000, for the same period last year. Shipments reached 75,938,000 bbl. for the first

seven months of 1923, compared with 61,879,000, for the same months in 1922. Compared with this time last year, the cement situation is one of increased production and shipments with a slightly smaller reserve stock on hand.

Brick—Report of the Common Brick Manufacturers' Association of America, as of Aug. 1, shows 179,574,000 burned brick on hand, at yards throughout the country, compared with 153,487,000 on July 1. Orders on books decreased 13 per cent in month. The drop in unfilled orders is purely seasonal, and leaves a better reserve of both burned and unburned brick than was available a month ago, but represents a decrease of 2 per cent under the amount on hand Aug. 1, 1922.

Los Angeles—Sewer pipe stocks normal. No shortage of lime or cement; mills active and constantly increasing capacity. Steady demand for brick, tile and structural steel being met promptly. Enough native asphalt for requirements. Large lumber supplies at harbor.

Denver—No surplus of hollow tile and sewer pipe at present. About 5,000,000 brick in dealers' yards. Lumber stocks trifle below normal.

Minneapolis—Lumber reserves in Twin City field reported close to normal; probably 50,000,000 to 60,000,000 ft. in yards, which is slightly below par for season. Stocks of lime, cement, brick and tile continue ample.

Detroit—Plenty of sewer pipe in sizes up to 36 in.. Cement scarcity reported on nearby road contracts; no actual shortage in city. Ample warehouse stocks of lime. Large brick reserves in local yards. Tile deliveries require several days where large quantities are involved. Lumber yard stocks normal.

Chicago—Sewer pipe stocks low; deliveries take 24 hr. Hollow tile re-

serves below normal; deliveries require one week to ten days. Sand and gravel shipments in two to three days. Other materials in good demand and plentiful.

Cincinnati—Plenty of sewer pipe, asphalt, lime, brick and hollow tile. Cement scarce. Fair supply of lumber in dealers' yards.

New Orleans—Stocks of Southern pine still below normal; other building materials ample.

Atlanta—About fifty cars each of lime and cement; seventy-five, of asphalt and from four to six cars of structural steel on sidings. Sewer pipe and hollow tile deliveries take from four to five days. Plenty of brick and lumber.

New York—Considerable quantities of brick from Germany and Holland reported to be coming into this market. Thus far, the importations have had no effect upon the price of the domestic product. Except for slight shortages in sewer pipe and steel plates, the building materials market in this city faces no danger of scarcity.

Freight Car Loadings Smash All Previous Records

All previous records were eclipsed in the loading of revenue freight during the week of Aug. 25, according to figures made public last week by the Car Service Division of the American Railway Association. The total for the week was 1,069,932 cars. This exceeded by 28,888 cars the previous record which was established during the week ended July 28 this year, when 1,041,044 cars were loaded. This also exceeded by 51,393 cars the record of 1,018,539 cars established in the fall of 1920, and which stood until this year. The total for the week of Aug. 25 made the tenth week this year that the million-car mark has been exceeded, and in six of the ten weeks the total exceeded the record established in 1920.

Despite the fact that loading of revenue freight for the week of Aug. 25 was the greatest in the history of the nation, the railroads on Aug. 23, the latest figures available, had nearly 75,000 surplus freight cars in good repair and immediately available for service, while on the same date the car shortage reported amounted, only to 7,690 cars.

CONDITIONS OF MATERIALS STOCKS IN IMPORTANT CENTERS

Stocks on hand in approximate figures, example: (Common brick, Denver, 5,000,000); time required for delivery of earload lots to city job, example: (Sewer-pipe, Atlanta, 4 to 5 days); and stocks on hand in general terms, example: (Cement, Cincinnati, scarcity).

	Los Angeles	Denver	Minneapolis	Detroit	Chicago	Cincinnati	New Orleans	Atlanta	New York
Sewer pipe.....	Stocks normal	No surplus	Ample	Plenty, sizes up to 36 in.	Stocks low; del. 24 hr.	Plenty	Abundance	Del take 4 to 5 days	Shortage
Cement.....	No shortage; mills active	Enough	Sufficient	Stocks decreasing	Stocks in good shape	Scarcity	Dealers' stocks large	About 50 cars	Mills supplying city steadily adding to daily capacity
Lime.....	No shortage	Plenty	Enough	Warehouse stocks ample	Plenty	Ample	Plenty	About 50 cars	Market well supplied
Common brick...	Demand met promptly	5,000,000	No shortage	Local yards well stocked	Heavy reserve of burned brick	No scarcity	Enough to fill requirements	Plenty	Considerable quantities of German and Dutch brick in market
Hollow tile.....	Meeting demand	No surplus	Requirements met	Dealers' stocks moderate	Below normal; del. 1 wk. to 10 days	Enough	Ample	Del take 4 to 5 days	Shipments meeting demand
Lumber.....	Large supplies at harbor	Trifle below normal	50,000,000 ft. in yards	Yard stocks normal	Dealers' stocks in good shape	Fair supply in yards	Improved during month	Plenty pine	Time of delivery good
Asphalt.....	Enough for requirements	Sufficient	Plenty	Enough in stock	Plenty	Plenty	No market	About 75 cars	Heavy reserves in N. Y.
Structural steel...	Little delay in deliveries			No shortage	Mill shipments exceed book-ings	Fair stocks of fabricating materials		About 4 to 6 cars	Low stocks of plates in warehouses

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 143 to 158, are the following:

Hotel, New York, N. Y., G. F. Pelham, archt. and engr., \$2,000,000.

Hotel, Ashland, Ky., for Buckingham Hotel Co., \$1,325,000.

Home and infirmary, Louisville, Ky., for St. Joseph's Infirmary, \$1,000,000.

Apartment, Philadelphia, Pa., for 13th and Locust St. Realty Co., \$1,000,000.

Hotel, Duluth, Minn., for C. Schroeder & Sons, Milwaukee, Wis., \$1,000,000.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 143 to 158, are the following:

Bridge, Solano to Contra Costa Counties, Calif., to Duncanson-Harrelson, San Francisco, \$4,500,000.

Hotel, Seattle, Wash., to Grant, Smith & Co., \$4,000,000.

Bridge, Charleston, S. C., to Sanford & Brooks, Baltimore, Md., \$1,067,466.

Home and infirmary, Buffalo, N. Y., to H. Schenk, Erie, Pa., \$1,079,000.

Breakwater, Toronto, Ont., to R. Miller & Sons, \$1,030,000.

Building Active in St. Louis

Building permits aggregating \$2,371,005 were issued by the St. Louis Building Department during August, bringing the year's total to \$25,705,355 or approximately \$500,000 more than for the whole of 1922. In August, 1922, a total of 1233 permits for \$2,206,670 were issued. The past month's total shows a slight falling off compared with July when 1393 permits for \$2,906,463 in work were issued. Of the August permits 974 were for new work valued at \$1,940,935 and 666 permits for repairs cost \$430,470.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted. Valuable suggestions on costs of work can be had by noting actual biddings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Sept. 6; the next, on Oct. 4.

Steel Products:	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal
Structural shapes, 100 lb.	\$3.64	\$4.00	\$4.20	\$3.40	\$3.55	\$4.20	\$3.60	\$4.10	\$4.00
Structural rivets, 100 lb.	4.40	4.75	4.90	3.75	4.25	5.40	5.00	4.75	6.00
Reinforcing bars, $\frac{3}{4}$ in. up, 100 lb.	3.54	3.50	3.80	3.20	3.45	3.85	3.65	4.10	3.90
Steel pipe, black, $2\frac{1}{2}$ to 6 in. lap, discount.	44% ^c	+45% ^c	45% ^c	47% ^c	53-5% ^c	36% ^c	33.2@42.2% ^c	35% ^c	-47.23
Cast-iron pipe, 6 in. and over, ton.	+63.60	+60.00	63.00	60.20	60.50	69.00	62.00	62.00	60.00
Concreting Material:									
Cement without bags, bbl.	2 70@2.80	3.00	2.25	2.20	2.50	2.84	2.63	2.90	2.25
Gravel, $\frac{3}{4}$ in., cu.yd.	1.75	1.90	2.38	2.00	1.85	1.90	2.15	1.25	1.50
Sand, cu.yd.	1.25	1.24	1.89	2.00	1.25	1.00	1.50	1.25	1.25
Crushed stone, $\frac{3}{4}$ in., cu.yd.	1.75	2.00	2.83	2.00	2.25	3.50	2.15	3.00	1.90
Miscellaneous:									
Pine, 3x12 to 12x12, 20 ft. and under, M.ft.	-61.00	40.00	52.25	+58.50	+44.75	+44.25	-38.00	+29.00	70.00
Lime, finishing, hydrated, ton	18.20	22.50	22.00	20.00	25.50	24.00	22.00	24.00	21.00
Lime common, lump, per bbl.	3.00@3.25	1.50	2.35	1.50	1.50	2.70	2.10	2.80	10.00
Common brick, delivered, 1,000	23.65	-11.00	13.10	11.00	17@19	12.00	15.00	13.00	16.50
Hollow building tile, 4x12x12, per block.	Not used	.102	.115	.0724	.0816	.06511	.115
Hollow partition tile 4x12x12, per block.	-1263	.102	.115065	.108	.11
Linseed oil, raw, 5 bbl. lots, gal.	-95	-98	-1.10	1.14	-.99	-1.09	1.16	.86	-1.22
Common Labor:									
Common labor, union, hour.75	.3550@.55	.55
Common labor, non-union, hour.30	.30@.50	.82 $\frac{1}{2}$.50@.55	.35@.50	.50	.50@.62 $\frac{1}{2}$	-.30

Explanation of Prices—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or - signs. For steel pipe, the prevailing discount from list price is given; 45-5% means a discount of 45 and 5 per cent. Charge is 15c per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. Labor—Concrete laborers' rate, 93c.; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu.yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5 $\frac{1}{2}$ x 8 x 11 $\frac{1}{2}$. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 97.56). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.23; 6-in., \$119.

Changes Since Last Week

Firmer tendencies in lumber and cast-iron pipe and a decided downward trend in linseed oil, characterize the current construction materials market.

Although pine timbers dropped \$2 in New York and Douglas fir, \$3 per M. ft. in San Francisco, during the last two weeks, fir advanced \$1 in Minneapolis and Seattle and \$1.50 in Denver, while pine rose \$2 per M. ft. in Chicago.

Owing to heavier flaxseed receipts,

raw linseed oil dropped 2c. in Atlanta; 3c. in New York and Minneapolis; 4c. in Dallas and 16c. per gal. in Denver, during last two weeks.

Gasoline is reported selling in Seattle at 16c. per gal.

The iron and steel situation may be briefly outlined as follows: Pig-iron prices stiffer owing to slowdown in production. Structural steel demand growing; lessening in car material requirement. Unfilled plate tonnage high.

Tank plates and bridge material fairly active. Price of plates and shapes steady at \$2.50 per 100 lb., Pittsburgh; premium of \$2 per ton required on early deliveries in many instances. Bars firm at \$2.40 base.

Cement continues to maintain its price stability; few changes being noted. Fordwick, Va., mill, however, quotes to contractors, in carload lots, f.o.b., without bags, at \$2.20 as compared with \$2.10 per bbl. one month ago.

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

Volume 91

NEW YORK, SEPTEMBER 20, 1923

Number 12

No Structural News from Japan

JAPAN continues to be cut off from the rest of the world except for some stories which the local reporters consider to have "human interest" and the necessarily colored impressions of those survivors who got away after the first few minutes of the shocks. Efforts are being made by this journal and others to assure an adequate statement of the effect of the earthquake and fire on the modern structures of Tokyo and Yokohama but it will probably be some time before such accounts emerge from the destruction. Meanwhile, from the scattered information available it is becoming increasingly probable that those structures designed to meet the tremors characteristic of the island have, on the whole, justified their design.

Who Gets the Dollars?

FACTS about the coal industry far more accurate and elaborate than ever made public or even known are in the possession of the Federal Coal Commission. They are being issued gradually, partly, it may be assumed, in order to gain continuous publicity but largely because of the difficulties in the actual preparation of the data in understandable form. Some day the whole story will possibly be available in book form so that one with sufficient time and interest may be able to discover why coal costs so much. Just now, however, the consumer is floundering in a sea of statistics sure only of one thing—that coal will be no cheaper. Cannot the commission particularize more than it has? Cannot it state whether royalties are too high, or at least how high they are, and whether wholesaler and retailer are making more today than the average increase of commodities since the price rise began? We have a statement of the wholesalers that their net profit in 1921 was six-tenths of a cent per ton. This sounds so ridiculous that it requires official answer. If in the turnover in which someone makes more money between mine mouth and cellar bin than it costs to mine the coal and pay its capital charges the wholesaler makes less than a cent a ton, who is getting all the rest of the money. The public wants to know.

An Act to Restrict Engineering

THE State of New York will not help a boy to get an engineering education. That, in effect, is the result, apparently just discovered, of the engineers license law that went into effect in that state last month. New York is very generous with scholarships, five worth each \$100 a year being annually awarded in each assembly district. In the past many of the boys winning these awards have studied engineering at one of the several engineering schools in the state, and have gone out to become successful engineers. Beginning this year, however, no more scholarship holders

will study engineering because of a clause in the enacting law which states that no scholarship "shall include professional instruction in theology, or in any profession, admission to the practice of which shall require a license from the state." Nobody seems to know why the law includes this general professional exclusion, but it should be noted that it operates almost exclusively against the engineer, because law and medicine—the other licensed professions—either require post-graduate courses or can be taken as undergraduate electives in the regular arts course, with some subsequent time for which the scholarship would not be applicable. On the other hand engineering courses are all plainly labeled as such and are almost exclusively undergraduate with small opportunity for election from an arts course. The advocates of licensing never foresaw any such ridiculous restriction, as this. Surely some effort should be made to amend the law so as not to discourage the study of engineering.

Marking Road Routes Through Chicago

TOURISTS more frequently lose themselves in large cities than in the country where the main traveled road has fewer competitors to engage the drivers' eye. Picking the proper streets through Chicago has always been a difficult and more or less dangerous procedure, for the through-route connections just inside the city limits have rarely been maintained in passable shape nor has there been any kind of marking within the city limits at all comparable with the average down-state county seat. All this is to be changed. Many of the connections have been repaired this season. As for signs, state highway engineers, county and city officials held a conference recently and decided on a generous sprinkling of uniform aluminum markers along the accepted routes, a zero point at Michigan Avenue and Jackson Boulevard from which mileage for all the radiating roads will be computed and a series of large direction markers. Many another large city could well afford a few dollars for signs of the same type as used on the official highways outside its limits for the satisfying familiarity of the recurring uniform signs is one of the most assuring welcomes the stranger gets from a city through which he drives.

Contractors Need Rail Records

IRREGULAR rail deliveries are an outstanding cause of rehandling materials on construction operations. Railways have the cunning custom of bunching materials cars, coming from several directions to a single consignee, at some convenient transfer point and then delivering them as one trainload. A contractor has for example track and unloading facilities for ten cars a day. For two days he gets no cars from the railway and the next day he gets twenty and his sidings and

unloading equipment are overwhelmed. To escape demurrage charges and the clamor of the railways, backed by the public service commissions, to release open-top cars for coal shipments, cars are, in such contingencies, unloaded where they stand and the materials are rehandled to the regular storage piles or warehouses or to the operation. This is not an imaginary case. There are few highway contractors who cannot cite one or more and generally several instances of bunched deliveries, with all the related consequences, during the present season. Arising out of this situation is one great gain. Contractors are keeping accurate records of car supply, shipping time, deliveries, and unloading periods. By doing this they are not only learning the causes of irregular deliveries and how they may be lessened, but they are helping to do away with the old subterfuge of "unloading delays" behind which the railways have been accustomed to shelter themselves against complaints of slow and irregular shipments of construction materials. A contractor who can support his complaint of poor service or defend himself against a charge of holding up cars by slow unloading with complete shipping records is in a very advantageous position before a public service commission.

Blocking Water Power Use

PRODUCTION of electrical energy by water power has a hard road to travel with the public. There is a deep-seated impression that it costs very little to develop water power and that it is only some inexcusable lethargy on the part of financiers and engineers that has prevented its complete supplanting of steam power. At the same time, in curious contrast to this, every effort to develop water power is met by violent opposition by the same type of mind that wonders at its slow progress—an opposition apparently grounded on the theory that all power developers are foes of the people who in some way are going to make money out of the public domain and resources without recompense to the public and with the greatest possible damage to natural beauty. In New York State today a typical case has arisen in the opposition by a group, who may with no derogatory intent be called "nature lovers," to a constitutional amendment permitting 3 per cent of the Adirondack state lands to be used for power purposes. Unless such an amendment is adopted the cost of transmission of power from the upper rivers to the power using centers will be prohibitive. Furthermore, only 3 per cent of the land is to be so used and that under the regulatory control of the state. And yet the pamphlet issued against the amendment could not be more violent if a group of medieval robber barons were contemplating forcible occupation of the whole of the state. Evidently we are going to be forced to an even higher cost of fuel than that we now enjoy before the serious need of power development is going to be appreciated.

Rehandling Construction Materials

MATERIALS are too frequently rehandled on most construction operations. It takes time and labor to place and then remove to another place sand and stone and lumber and steel. This is a lesson which has been more thoroughly learned in manufacturing than in constructing. To carry most construction materials through the processes absolutely necessary to transform

them from raw materials to finished structure requires seven or eight handlings. In factory operations the mechanical conveyor is widely used to facilitate these necessary movements of materials. There is doubtless less opportunity for its use in construction but still too much shifting is done by "strongarm" methods. Too often does one see on large construction operations sacked cement, for example, being shifted from cars to warehouse and from warehouse to the mixer or the service trains on men's backs or by barrows when a few sets of roller conveyors would save men and time. It is, however, the unnecessary handlings which most need to be reduced in construction. A material is unloaded from cars and piled only to be shifted and repiled nearer to where it is used. Lumber and reinforcing bars are unloaded into piles and then sorted out and repiled according to lengths and sizes. Illustrations could be repeated endlessly. Each handling of a construction material which thus does not advance its fabrication into structure is a non-productive expense. Contractors need to study more than they always have done, ways of eliminating these non-productive expenses. No thought is had that the automatic methods of turning out Ford cars can be applied to the operations of road building or bridge erection, but nevertheless it would help to cheapen their materials handling operations if contractors would give some study to factory processes.

Buffalo's Garbage Disposal Predicament

HOW far even our larger cities are from handling garbage disposal in a proper engineering manner is strikingly illustrated by the way Buffalo has dilly-dallied with its local garbage disposal problem for several years past and the predicament in which it now finds itself in consequence. In but one detail did the city authorities act effectively; they do have to their credit the calling in of a competent sanitary engineer for advice on garbage disposal bids but they delayed doing this until after bids had been received on such very open specifications that the engineer called in was compelled to spend much time and go into extensive calculations in order to reduce the bids to a comparative basis.

Although this engineer's report had been before the commission council at Buffalo for months past, and endorsed by the city street commissioner and by the council commissioner in whose department garbage disposal falls, the commission has not acted upon these recommendations. Meanwhile, as has been perfectly apparent for a considerable time past might happen, the city has been ordered by the court to shut down its garbage piggery on allegations that it is a nuisance. This order was to become effective Sept. 15 but the city authorities have secured a hearing for Sept. 26 on an application for a modification of the order and in addition have taken steps to carry the order to a higher court. It is to be expected that the complainants against the piggery will press for shutting it down and that if the court grants the city relief, it will be only because of sympathy for the city in its predicament and because if the plant were closed nuisance might be caused to a far larger number of Buffalo people as a result than would be caused to the relatively few people near the piggery if it were kept in operation.

The Buffalo example is so flagrant a one of failure by a city to see that garbage disposal must be handled

as an engineering problem if grave complications and possible large and unnecessary expense are to be avoided that we present to our readers a condensation of the very exceptional report on the Buffalo bids prepared by H. P. Eddy. The specifications on which bids were asked were so vague and so lacking in the many requirements necessary to make the bids comparable that, as one of our tables shows, revised estimates of cost for a 200-ton plant were far in excess of the proposals; in one case nearly four times as large. Additional calculations were required before Mr. Eddy could reach conclusions as to which method of disposal, among those offered, seemed most desirable. Before reaching this point, Mr. Eddy found it advisable to eliminate entirely all of the bids for garbage disposal by incineration. He also found it necessary to double the city specification allowances for the size of a plant for treating unclean garbage and hog manure in case a piggery was decided upon.

In passing it may be noted that what will perhaps be to most engineers a matter of great surprise is that after careful consideration Mr. Eddy concluded that in case feeding to hogs were to be adopted, it would be wise to provide a disposal plant for the residue one-half of the daily capacity of the total estimated amount of garbage collected.

The most valuable of all the advice Mr. Eddy has given to the city of Buffalo in this matter, if only the city will heed it—and it is advice that every other city in the country confronted with garbage disposal problems should take to heart—is that the city should decide on some one scheme of disposal, have complete designs made, and then obtain bids for the construction of a plant of that type and size and none other. This is directly opposite to the general practice of American cities. City authorities generally do not put the matter of garbage disposal in the hands of their own engineering force or of competent consulting engineers, have a plan designed and specifications drawn and then ask for bids, all on such a basis of site, size of plant, contract guarantees, test requirements and total annual charges, as will make it possible to compare the bids received understandingly.

Few, if any, cities—and none we hope as large as Buffalo—would think for a minute of asking bids for a pumping station or a filtration plant, to name only two kinds of engineering work, on such vague specifications as those on which the Buffalo garbage disposal bids were based. How indefinite these specifications were may be seen in part from our abstract of Mr. Eddy's report. Had the council commission of Buffalo attempted to award the contract on the basis of comparative bids received—and many another city has done just this sort of thing—it would almost certainly have been sadly disappointed in the results that it would have obtained when it came to count up the actual cost of installing the plant and the total annual charges.

Finally, we regret to have to say that some cities which confine their request for bids to one general type of means of garbage disposal improve upon the Buffalo specifications in degree only; that is, although they may eliminate utterly different methods of doing the same sort of work, they provide neither adequate detailed specifications or contract guarantee and acceptance tests that will indicate with any certainty what the plant will really accomplish in daily operation.

It is high time that our cities make some change in their methods of treating garbage disposal. It is to be hoped that after its present experience, Buffalo before again advertising for bids will follow Mr. Eddy's advice as to definite plans and specifications for one type of plant. Judging from reports of commission council proceedings since Mr. Eddy's report was submitted, the commission council has not yet seen this matter in its full and true light.

General Service Equipment Economies

PROCEDURES which have almost the characteristics of principles of plant engineering were followed in planning the construction plants for the Delaware River Bridge anchorages described in this issue. The conditions of the specific problem at Philadelphia and the lines of reasoning which naturally followed need not be repeated. Outstanding from the details are: (1) Selection of plant units to permit interchange of duties; (2) provision for intra-operation mobility of these units, and (3) consideration of their future utility. All these are ideas of an economic significance which reaches beyond any specific piece of construction work.

Specialization of construction equipment has proceeded so far and produced such great economies that when large volumes are involved it requires a wrench to separate our minds from the thought that necessarily large-capacity special machines are the universally logically selection. In the Delaware River Bridge anchorages there was a large volume of excavation to be removed, and a larger volume of concrete to be put in place. Considering volume alone either the excavation or the concrete placing warranted large-capacity special equipment. It was not adopted for sound economic reasons. Alternation of excavating and concreting operations made the output capacity and speed of special machines of no benefit. This is a condition which frequently prevails in construction operations; the aggregate volume of each kind of work is large but the volumes which can be accomplished as continuous operations are small.

Again, as at Philadelphia, the alternations of operations are frequent in many construction processes. On the bridge anchorages excavation, concrete placing and a period of rest for the concrete to harden was the succession continuously repeated. The only plan by which equipment can be kept busy under such conditions, which incidentally are common in many classes of construction, is to keep it moving from one structural unit to another. This requires intra-operation mobility which exceeds mere ability to move the equipment units easily and approaches a continuous circulation of equipment, such as on the anchorage work was provided by interconnecting tracks, locomotives and traveling cranes.

General service equipment met the conditions better than could any special equipment however superior that might be under conditions which permitted its full efficiency. Furthermore it possessed a greater salvage value. It was usable plant for future operations of great variety. With this we have a summation of values which the contractor should appraise carefully in outfitting a construction operation—ability to shift from one duty to another and from one point of operation to another and, finally, salability as second-hand equipment.

Anchorage Construction Plant, Delaware River Bridge

Sequence of Changing Operations Handled by Mobile Units on Overhead Track System
Transport by Scows Solved Problem of Limited Land Area for Storage

BUILDING the anchorages for the Delaware River Bridge called for careful planning of the construction plant. The structures and their location were closely alike, the quantities were large, the kinds of work varied and the main processes had to be performed alternately. Combined with limited working room and congested means of transportation except by water, these conditions made plant layout a serious consideration. The contractors met the situation by installing (1) a loading and unloading station and a concrete mixing plant on the river front, (2) a service railway

Combining the two sets of figures the main quantities are as follows:

Item	Camden	Philadelphia
Concrete, cu.yd.	76,930	58,130
Excavation, cu.yd.	48,150	36,500
Anchorage steel, lb.	2,322,000	2,322,000

One fact further requires notice; the caissons are open—reinforced concrete shells and partitions sunk by dredging from the inside and built up as sinking proceeds. Their structural character is shown clearly enough by any of the views.

General Conditions—With the structures and quantities as outlined, the general conditions were as follows:

1. There were to be built on opposite sides of a wide river two structures identical in character and involving approximately the same quantities. The contractor for these structures was also the contractor for the adjacent piers and had plant installed and work well advanced on the piers when the anchorage contracts were secured.

2. There was available on each side of the river a working area not greatly larger than the horizontal projection of the bridge structure between pier and anchorage. The anchorage structures virtually covered the sites purchased for anchorages. Both piers were in the river. On the Philadelphia side the anchorage was inland and between it and the pier the bridge area was occupied largely by a busy waterfront street and approaches to pier sheds and ferries. On the Camden side the anchorage was on the river's edge and between it and the pier was open water.

3. Railway track service to the anchorage sites was not easy to secure on either side but more particularly on the Philadelphia side. There was on either anchorage site no adequate track and storage yard room for materials and supplies or for disposing of excavated material. In contrast the river offered a natural means of bringing in material and taking away spoil, with the advantages of complete flexibility of movement, large cargo shipments and low rates.

From the general conditions it appeared, conclusively, that (1) two similar construction plants were required; (2) the river should be the way for bringing in material and removing excavation and (3) the plant for pier and anchorage should be combined as far as practicable. With these general conclusions reached, the operations which the plant would be required to perform came up for consideration.

Controlling Operations—Obviously the controlling processes were (1) removing excavated material from the anchorage emplacement and (2) putting concrete into the anchorage structure. Incidental to excavation and producing and placing concrete were the operations of handling forms and reinforcing steel and of

FIG. 1—PLAN AND ELEVATION OF ANCHORAGE SUPERSTRUCTURE

on trestle from the river front installation to the anchorage site, and (3) an overhead crane-track and service-track system covering the anchorage site. This arrangement was approximately duplicated for the two anchorages.

Anchorage Structure—In general design the anchorages are alike. Each consists of a superstructure, Fig. 1, approximately identical and of a substructure of reinforced-concrete caissons filled with concrete. There are ten caissons for each—two rectangular and eight circular. The quantities in the two superstructures are nearly the same:

Materials	Philadelphia	Camden
Concrete, cu.yd.	29,630	29,930
Reinforcing, lb.	239,900	223,000
Anchorage steel, lb.	2,322,000	2,322,000

In the caisson substructures the differences are greater because the rectangular caissons on the Camden side are larger and their depths to rock are different. The substructure quantities are approximately as follows:

Materials	Camden	Philadelphia
Concrete, cu.yd.	47,000	28,500
Open pit excavation, cu.yd.	1,150	8,000

FIG. 2—LOCATION PLAN OF PIERS AND ANCHORAGES

FIG. 3—DETAIL PLANT PLAN FOR PHILADELPHIA ANCHORAGE

installing the anchorage steel, and finally, miscellaneous materials handling. Analysis of the several operations brought out a number of facts affecting plant selection and arrangement.

The excavation did not call for the quick handling of large volumes. About seven-eighths of the yardage had to be taken from caisson wells and in the case of the large caissons, with numerous wells, removal had to be divided evenly between them all. This made the process necessarily slow. There followed then the necessity of accumulation in piles or of holding shipping units some time in receiving the load; and as has been pointed out there was no room on the anchorage sites

for either procedure. In the same way, concreting any particular caisson unit was a slow process—each lift of a few feet required only a moderate yardage, had to be hardened and get strength and the caisson had to be lowered before another lift could be concreted. To get output, then, in either excavation or placing concrete, it was necessary to put all the caissons under way and to shift work from one to another so as to keep both operations practically continuous.

Plant Planning—Plants had been installed for building the bridge piers. Each consisted of bins, mixer, hoist tower and chutes and equipment for unloading scows and for loading excavated material into scows.

FIG. 4—DIAGRAM TRACK PLAN FOR CAMDEN ANCHORAGE

Both were located on the ends of shipping piers reaching outshore to points close to the bridge piers (Fig. 2). Substantially the same equipment units and plant functions were necessary in building the anchorages. It was, therefore, planned to trestle from the pier plants to the anchorages and over the anchorage sites as shown by succeeding drawings and views; to lay elevated service and crane tracks on the trestle, and to install locomotive cranes and narrow-gauge locomotives and cars.

In general the plan was the same for both anchorages.

or other materials either in single carloads or in train loads of as many cars as may be needed.

Extension of the services of the pier construction plants to the work of anchorage construction supplemented the flexibility of the trestle outfits. By water materials could be received and spoil removed with almost complete independence in respect to time or volume. There was no problem of storing material on the construction site. By the trestle also the streets were kept clear of contractor's traffic.

FIG. 5—PHILADELPHIA ANCHORAGE, NORTH CAISSONS, LOOKING EAST

Fig. 3 shows the complete layout for the Philadelphia operation. Here there was no possible access to the anchorage from the rear and access to the elevated track system is by a ramp from railway tracks on Delaware Ave. On the New Jersey side the only approach to the anchorage site was from the rear and here the incline to the elevated track system was built as indicated in diagram by Fig. 4. Figures 5 and 6 are views of parts of the two anchorage plants during caisson sinking—track system, equipment and structure are clearly indicated. The track system is so arranged that every part of the anchorage structure is put within reach of a locomotive crane and a service train. Indeed almost complete flexibility has been secured, as shown by:

1. The cranes can excavate with clamshell, place concrete, shift forms, handle reinforcement and anchorage steel equally well and they can be grouped and scattered as the operation requires.

2. The service trains can handle concrete or spoil

Construction Methods—Methods of construction are interesting chiefly in connection with sinking and seating the caissons and they are not completed and are a subject for separate consideration. As affecting plant, construction is a sequence of changing operations. For example excavation proceeds from inside a caisson until the shell has gone down a certain distance and then excavation is discontinued so that the caisson can be built higher. This is the entirely different process of concrete construction, including form erection and placing reinforcement and concrete, followed by an interval of idleness while the construction is getting strength. Then excavation is resumed. Repeated for ten caissons distributed over an area 148 x 218 ft., these operations call for constant shifting of duties. The case will be the same in superstructure construction where placing concrete will alternate with the processes of very precise erection of anchorage steel. The requirements, it was considered, were best met by a plant of many units

which could be separated or combined as desired, providing a substantial freedom of movement.

In operation the arrangement has been successful. It has been possible to keep the caissons progressing quite uniformly and so to schedule procedure that there is little idle plant time. Another economic feature is that, with the exception of some of the steel form units, there is hardly an item of plant which is not of general usefulness in construction operations of numerous kinds.

Directing Organization—The construction of the

Sanitary Engineering on the Cotton Belt Ry.

UNDER THE heading of "Activities of Sanitary Engineer" the annual report of St. Louis Southwestern Ry. contains the following statement on malaria control work:

"Malaria control work conducted by this department was continued throughout the year with success. The distribution of quinine in prophylactic doses was ex-

FIG. 6—CAMDEN ANCHORAGE LOOKING WEST

Delaware River Bridge is in charge of a board of engineers of which Ralph Modjeski is chief engineer and George S. Webster and Laurence A. Ball are members. Clement E. Chase is principal assistant engineer and M. B. Case is senior resident engineer. The contractors are the Keystone State Construction Co., and Holbrook, Cabot & Rollins Corp.

New Concrete Ties Used in India

The Northwestern Ry. of India has made exhaustive tests of a new type concrete railway tie patented by a Delhi consulting engineer, says a recent report to the Department of Commerce from the Calcutta vice-consul. Use of the tie on 50 miles of track near Delhi has been so satisfactory that 70 more miles are to be similarly equipped. The tie consists of two concrete blocks joined together by a tiebar, the rails being fastened by means of a screw or dog spike driven into wooden plugs, treated and compressed, inset in the concrete block.

tended to track employees on 831 miles of the operated mileage.

The effectiveness of this method of malaria prevention is evidenced by the fact that only 24 section men were admitted to the hospital suffering from malaria, compared with an annual average admittance from this class of employees of 259 prior to the inauguration of malaria control. During the year a total of 98 malaria cases were treated at the company hospital.

This is a decrease of 504 compared with the average number treated during the four years prior to malaria control. Through the influence of this department the cities of Pine Bluff, Ark., and Hillsboro and Wells, Texas, inaugurated a malaria control campaign, and the interest of other cities and towns has been maintained through malaria essay contests conducted in the schools and through contact with educators and city and public health officials."

Concrete Pipe Irrigation System Delhi Settlement

Million Feet of Pipe Being Laid by California State
Land Settlement—Buried Sand Traps
and Other Features Described

By JOHN R. JAHN

Irrigation and Land Settlement Engineer, Berkeley, Calif.

THE CONCRETE pipe irrigation system at Delhi, near Merced, Calif., has many interesting features and is effecting marked economies in operation. Although there are but 8,500 acres in the settlement there will eventually be in use a million feet of pipe ranging in size from the 30-in. mains to 8-in. laterals. This is being laid in units of some 250,000 ft. per year, keeping ahead of the allotment of the land to settlers. The system is complete from the diversion structures for the gravity water supply, at the canals, and the

lines are so looped, and controlled by gates, that one area may obtain water from another and different sections be supplied either by gravity or pressure.

The concrete pipe is made in an enclosed plant having air tamping machinery for sizes of 18 to 30 in. and a Brubaker pipe machine for sizes of 6 to 16 in. Among the novel features of this plant are the Lowden overhead carrier for moving the pipe on trays from the Brubaker machine to the curing yard, and the Skinner overhead spray system for keeping the pipe moist while curing. The inclosed plant protects the pipe against the extreme temperatures of summer and winter.

The pipe is laid in trenches cut to sufficient depth to have at least 18 in. of earth cover. For 18-in. pipe and smaller, the excavation is done by hand on a piecework or per foot basis. A power excavator is used for the larger pipe. The pipe is laid by contract, the contractor furnishing the laying materials with the exception of sand. The settlement district hauls the pipe and distributes it along the prepared trenches. The pipe is laid, joints banded with mortar and backfilled to a depth of 3 in. over the pipe by the laying contractor. The remainder of the backfilling is done by hand or with stock on a piecework or footage basis.

The following unit costs per completed foot of line are used as a basis for estimates:

Size of Pipe, Inches	Price per Foot, Cents
8	33.4
10	41.3
12	55.3
14	70.8
16	83.7
18	109.0
20	155.6
24	192.5
30	303.6

The maximum pressure head on any main line is 45 ft. but there are many instances of pressure heads which range from 20 to 40 ft. In 1920 it was the practice to place electrically welded rings of No. 6 steel wire ($\frac{1}{2}$ -in.) within the pipe shell for reinforcement but the difficulty of centering these properly led to the adoption of other methods. The pipe to be used under pressure heads greater than 15 ft. are now wrapped outside with rings of No. 2 ($\frac{1}{4}$ -in.) steel wire at the ends and center of each joint. By twisting the loose ends of the wire together the concrete of the shell is put in slight compression. These rings are covered with joint mortar for protection against rust. Another form of reinforcement that has been used consists of strips of $\frac{3}{4}$ -in. square mesh screen, 8 in. in width, encircling the pipe and encased in banding mortar. These bands are spaced 50 to 100 ft. apart on a pressure line to guard against extensive longitudinal ruptures. No pipe smaller than 14 in. is reinforced nor is any used on low pressure lines of larger sizes.

Among the special appliances developed in the construction of this pipe irrigation system attention is called to four types of structures: (1) Sealed gate chambers; (2) capped stands; (3) buried sand traps; (4) overflow syphon spills.

Sealed gates and capped stands are constructed in the pipe-making plant and moved by trucks to the field. They are complete with screw gates installed and have inlet and outlet pipe nipples for connection to pipe lines. The sealed gates have from one to four screw gates on their four inside faces while the capped stands seldom have more than one, which is placed over the

FIG. 1—COVERED THREE-COMPARTMENT SEALED
GATE CHAMBER

Boiler plate covers compress square hemp packing by means of stud nuts. Two of the screw gates do not show in this view

pumping plants, through the main distributing pipe lines and division boxes to the alfalfa or orchard valves on the field laterals. Water is distributed among the five hundred farm units by two or three water tenders.

The ground surface at the colony consists of gently rolling ridges and swales—about 40 per cent being above the elevations which could be supplied economically by gravity from the existing canals of the Turlock Irrigation District. The soil is a fine sand and canal seepage losses are high. These features, together with the increased economy of application of water and the saving of land for farming, led to the adoption of concrete pipe.

In designing the system a topographic survey was made of the land and contour maps were drawn having a scale 1 in. = 100 ft. These maps were in half-section (320-acre) units and showed about six elevations per acre with 1-ft. contours. These sheets were reduced by pantograph and combined to form a key map having a scale of 1 in. = 800 ft., with 5-ft. contours. The subdivision design was made on a basis of topography by aid of the detail sheets and was transferred to the key map. The distributing mains were laid out on this key map to serve every farm unit from at least one connection.

These main lines generally serve some areas which are above the gravity supply. Pumps are used: (1) to boost the gravity supply to the higher levels; or (2) to lift it from wells or from the Merced River. The main

inlet port. The object of these enclosed gate chambers is to provide cutoffs without high, open gate chambers, since they are often used where the hydraulic grade line stands 30 ft. or more above the ground surface. The capped stand differs from the sealed gate in that it is built up of sections of 18-, 20- or 24-in. concrete pipe, while the sealed gate requires collapsible inside and outside forms. The sealed gate has a cover of $\frac{1}{2}$ -in. boiler plate, held down by nuts on $\frac{1}{2}$ -in. bronze bolts. A ring of $\frac{3}{8}$ -in. square hemp packing between

FIG. 2—CAPPED STANDPIPE BEFORE BACKFILLING

the plate and the concrete body makes the chamber watertight. The screw gate stems pass through stuffing boxes which are acetylene welded to the boiler plate covers. Installed, the tops of these sealed gates are about even with the ground surface and the gate stems, which are of $\frac{3}{4}$ -in. wrought-iron pipe with special T handles and stand 2 to 3 ft. above the surface. A sealed gate with one 12-in. and two 10-in. screw gates, costs complete and installed about \$60. Access to the gates may be had at any time by closing the inlet gate and removing the nuts from the bolts which hold down the cover.

The capped stand was developed by Ernest Fortier and has proved very satisfactory. It has a good appearance in the field. A special ring form joins the cap and the stand. Hemp packing is used here and compression is obtained by screwing down nuts on the four rods which reach from a spider in the base up the outside of the pipe to a similar spider in the top. The cost of one of these, with a 12-in. gate, is about \$35, installed. There is usually enough space between the valve stem and the stuffing box to allow trapped

air to escape although some have been built with automatic air-vent valves.

Buried sand traps are used to remove sand from water which is pumped from the wells. Their advantage over those of the usual vertical type is that the water does not have to be lifted above the level of the ground surface to function. Ten feet or more of 24- or 30-in. pipe is laid horizontally 18 in. below the ground surface. Pump connection is made above the center line at one end and the sand flushing port is at the bottom of the other end. The discharge to the main line is taken from a riser in the sand trap 7 ft. or more from the pump connection and has a cutoff screw gate in the sealed gate chamber to allow water to pass on through the main line when desired. A standpipe of 10- or 12-in. galvanized-iron pipe relieves water surges. The economy of this type over the usual vertical chamber in which water is lifted over a dividing wall comes from a saving in power. It is estimated that the electric power used in lifting 500 g.p.m. 4 ft. higher than necessary during a seven months' irrigation season costs about \$30, which can be saved by the buried chamber type. The cost of this type of sand chamber, complete with flushing screw gate and vertical galvanized-iron surge pipe, is about \$200, installed.

A few words may be said concerning the wells of the settlement. The objects of these are to: (1) augment the gravity irrigation supply; (2) serve land above the economic gravity hydraulic grade line; (3) decrease the sizes of main lines; and (4) promote drainage by lowering the ground water table. They are located at strategic points and provide from 500 to 1,000 g.p.m. Suitable water-bearing gravel is found in different strata, the usual depth being 80 to 120 ft. The water table stands at 12 to 25 ft. and the economic draw down of from 25 to 40 ft. depends on the elevation of the ground surface.

The different types of pumps that have been used in the several installations are: (a) horizontal centrifugals; (b) vertical turbines; (c) vertical centrifugals. The latter type is being used for lifting water from the Turlock Irrigation District's canals and is so hung that the pump itself is submerged. All of the pumps are giving satisfaction, the different types being fitted to the different working conditions. Electric power is obtained from the San Joaquin Light & Power Corporation.

The overflow siphon spill and surge pipe, Fig. 3, was developed to protect the pipe lines against harmful increases in pressure, which might be caused by an irrigator closing his alfalfa valves without notifying the water tender. The novel feature is the inexpensive conical cap which connects the riser with the discharge pipe. The discharge pipe conducts overflowing water to safe waste-way. Normally the water stands in the riser at the hydraulic grade line. When the water level rises due to the closing of a valve, the water spills and falls as a simple overflow until a siphoning column is built up, when the discharge increases. The siphon is broken by the 4-in. opening at the point of the cap when the hydraulic grade line drops to that level. Were it not for this opening the siphon would not be broken until the hydraulic grade line fell to a point near the ground surface, thereby wasting water unnecessarily. The action of these siphon overflows is intermittently up to the capacity of the riser. One of these, with a 10-in. discharge pipe, has handled 1,000 g.p.m. without overflowing the open cap.

This pipe irrigation system has in many ways proven its superiority over open ditches. Its first cost is its chief drawback. This amounts to about \$36 per acre for the main distributing system, to which the farmers' private lines add about \$43. This is advanced

FIG. 3—SURGE AND OVERFLOW SIPHON SPILL, MERCED RIVER PUMPING STATION

the settler by the state but is repaid by him in amortized payments at the rate of about \$5 per acre per year, interest being 5 per cent on the outstanding principal.

The Delhi Colony is one of the California State Land Settlements carried out under Dr. Elwood Mead as chief of the division and Walter Packard as the Delhi superintendent. The system was designed and constructed under the direction of Milo B. Williams, chief engineer, assisted by John R. Jahn, Ernest Fortier, Lloyd Brown and others.

Increasing Traffic on Soo Canals

A report by the Dominion Bureau of Statistics of the canal traffic of Canada for June shows how intensively used are the Canadian and American canals at Sault Ste. Marie. In the thirty days there were 3,249 vessels locked through, of 10,069,109 registered tonnage, compared with 2,396 of 7,356,926 tons last year. There were 1,080,720 barrels of flour, 36,457,141 bushels of grain, 9,222,722 tons of iron ore and 3,323,875 tons of coal carried as freight through the canals.

Effect of Curing Methods on Concrete Roads

Tests of Various Methods of Curing Road Slabs to Determine Effects on Wear and Transverse Strength

By H. J. KUELLING

Construction Engineer, Wisconsin Highway Commission, Madison, Wis.

TO COMPARE field with laboratory conditions this series of tests was run both in the field and in the laboratory using like materials cured in a similar manner so far as practicable. The following methods of curing were selected:

1. Sodium silicate, applied with a pail and old floor brush, coating the entire surface uniformly. As stipulated by the company supplying the material, a mixture of three parts silicate and one part of water was used.
2. Calcium chloride, flake, applied three pounds per square yard of surface. This was applied with a shovel and spread out uniformly.
3. Calcium chloride, granulated, applied three pounds per square yard of surface.
4. Earth covering about three inches thick, kept constantly moist for two weeks.
5. Hay covering, about five inches deep, loose measure, kept moist for two weeks.
6. Straw covering, about five inches deep, loose measure, kept moist for two weeks.
7. No covering on the surface.

For the field operations a road near the city of Madison was chosen as it was reasonably close to the laboratory. The party was equipped with a light truck, scales, balance, thermometers, molds and small tools.

Method of Testing—Six slabs $4\frac{1}{2} \times 8 \times 19\frac{1}{2}$ in. and six 6×12 -in. cylinders were made from concrete cured by each of the above methods. Only one specimen was made from any given batch of concrete, but a slab and a cylinder were always made from the same batch.

The slabs were made by placing steel molds against the side forms of the road, the slab being removed after the concrete had set and the road form was removed. The holes resulting were filled the next day with standard concrete. After removal the slabs were placed, face upward, upon the adjacent pavement and cured by the same method as the roadway section. The sodium silicate and calcium chloride specimens were surrounded by dirt to prevent loss of moisture from the sides.

The cylinders were filled in sections of one-third, with material taken from different portions of the batch. Each layer was puddled with about twenty-five strokes of a half-inch rod. The top of the mold, after finishing and partially setting, was protected against evaporation by a canvas covering. The pasteboard forms, in which the cylinders were cast, remained attached to the cylinders until the day previous to breaking. They were marked with the identification of the corresponding slab.

The cylinders for the sodium silicate and calcium chloride were protected by dirt to prevent exposure to sun and air. The others were covered with their respective curing agents.

At fourteen and twenty-one days the slabs and cylinders were removed to the laboratory and tested.

Besides making the slabs and cylinders, the field party determined moisture contents, weights, proportions, and consistencies of the materials and resulting concrete.

The party also secured the samples of materials for the laboratory tests. These consisted of a sack of cement, about 250 lb. of fine aggregate and 375 lb. of coarse aggregate, each taken from the stock piles near the mixer at the time the respective field slabs and cylinders were being cast.

On reaching the laboratory with the material samples, colorimetric tests were run on the fine aggregate; the weight per cubic foot of both fine and coarse aggregate was determined after drying; a sieve analysis was run, and briquette tests were made on one part of cement to three parts of fine aggregate. Six slabs and six cylinders were made from each sample of aggregate and cement. For comparison purposes so-called "standard" specimens were made, which consist of a good limestone, a good sand and a mixture of three brands of cement, these materials all being in constant use in the laboratory. Great care was used to make these under as nearly equal conditions as possible, only one slab and cylinder being mixed at a time.

After one day in the molds, the cylinders were placed in the moist closet until the day of testing. The slabs to be cured with sodium silicate and calcium chloride were placed on a platform adjacent to the moist closet. The sides, ends and bottoms of these were sealed with sodium silicate and the top only cured in its respective manner. The slabs to be cured with hay, straw and dirt were placed in the moist closet, covered and moistened daily. The slabs and cylinders which were to have no covering were placed in the permeability room which had an average temperature of about 75 deg. F.

The slabs were withdrawn from the moist closet after 14 and 18 days. The 14-day sets were tested on removal, but the others were allowed to stand three days at room temperature.

The cylinders were kept in the moist closet 14 and 21 days and tested immediately.

In the field, six slabs and six cylinders were made of each method. Three were tested when 14 days old and three when 21 days old. The 21-day period was chosen because it is the standard of the Wisconsin Highway Commission, and the 14-day period was chosen to determine what effect the shorter period of curing had upon the strength results.

Sections cured by sodium silicate and calcium chloride were not touched after having the curing agent applied, which was about twenty hours after pouring. The sections covered with dirt, hay and straw were kept moist for 14 days, the standard Wisconsin practice. Sections not covered were exposed to the normal existing weather conditions, which had an average temperature of 72 deg. F.

The specimens, both field and laboratory, were broken under standard laboratory practice. The cylinders were crushed in a 100,000-lb. testing machine. The slabs were rattled in an abrasion machine quite similar to a standard brick rattler. Six slabs were tested at once, being fastened in like staves in a barrel. One stave was a dummy with slots in it to permit the accumulated dust to escape during the rattler operations. The charge consisted of 150 lb. of small iron shot and 50 lb. of large shot.

The charge was given 1,800 revolutions in a clockwise and 1,800 revolutions in a counter-clockwise direction at a speed of thirty revolutions per minute.

In making the transverse tests, the specimens were supported on rocker bearings over a 17-in. span with the

worn side of the slab down. (Slabs were first rattled and then broken for transverse strength.) The table shows the test results.

Results and Conclusions—From this table can be assembled various other tables, such as a comparison of strengths at 14 and 21 days of the various materials and curings; a comparison of field with laboratory speci-

WEAR AND STRENGTH OF PAVEMENT CONCRETE CURED BY DIFFERENT METHODS

Age in Days	Weight Lost, Per Cent	Mod. of Rupture, Lb.	Ult. Str. Cylinders, Lb.	Character of wear in rattler test of slabs

Note: In each case the figures are an average of three specimens except where slabs broke in the rattler and the modulus figures represent two specimens or less.

mens as to wear, transverse strength and compressive strength. These tables have all been drawn up, but it was felt that they would make this article too lengthy.

The consistency of the concrete was in most cases drier for the laboratory than for the field mixes. It is felt, however, that the amount of water retained in the field slabs when setting took place was less than the amount retained in the laboratory specimens, on account of the finishing operations and the weather action.

The important effect of the absorption of the subgrade will be appreciated from some laboratory tests which were made in 1921. Half of the specimens were bedded on sand and half made in tight cast-iron molds. These tests show that the slabs with sand bottoms were 5 per cent stronger in the transverse test and lost 5 per cent less in the rattler than the slabs made in the tight molds. Because of these reasons one would expect the field slabs to prove more resistant to wear and stronger in the beam test than the laboratory slabs, a condition which is true in nearly every case.

The field experiments show that the calcium chloride covered specimens give the best results for transverse

strengths in both the 14- and 21-day periods of curing, though closely followed by the strengths of the dirt covered specimens. The latter gave, on an average, a more resistant surface for both periods. Not so marked a difference was noticed between these two types of curing in the laboratory specimens.

In both the field made and laboratory specimens, cured by calcium chloride, the modulus of rupture dropped considerably at 21 days. Because of this rather startling defect some studied consideration should be made before the acceptance of this material as a curing agent.

Where dirt is available, it is preferable to use this material for a curing agent, rather than hay or straw. The latter could be used when dirt is not available.

By no means, as is clearly shown by these tests, should a newly poured surface be exposed to sun and winds.

It is evident from these tests that the concrete had gained sufficient strength to warrant the opening of the road to traffic at the end of fourteen days without possibility of doing injury to the pavement. In cases of extremely heavy vehicles damage might be done, but not with ordinary traffic.

Brick on Waterbound Macadam with Penetration Curb

Construction Methods on Twenty-Mile Texas Road—Curb Work Unique—Ten-Months' Traffic Develops No Defects

BY C. H. HENNING

State District Engineer, Texas Highway Commission

METHODS unusual in character and thoroughness have been employed in building a 20-mile brick road in Eastland County, Tex. This road leading from Granger to Cisco has a waterbound macadam base surfaced with vertical-fiber, asphalt-filled brick, edged with curbs of penetration macadam. It is a federal-aid project, F. R. Sexton being the government engineer

FIG. 1—CROSS-SECTION OF BRICK ROAD WITH PENETRATION CURBS

in charge, and is financed with 45 per cent county funds and 55 per cent state and federal-aid funds.

As shown by the drawing, Fig. 1, the roadway is 28 ft. wide on fills and 38 ft. wide in cuts. The base is 8 in. of thoroughly compacted macadam 19 ft. wide, with a 2-in. crown. Upon this base and a 1-in. sand bedding course is laid a surfacing of 3-in. vertical-fiber, vitrified brick to a width of 17 ft. Asphalt filler is applied, with the thinnest possible coat remaining on the surface, after which coarse sand is applied.

On each side of the 17-ft. brick surface and on top of the remaining foot of 8-in. base a 4-in. asphalt macadam shoulder is constructed. This shoulder is 1 ft. wide and is designed to serve in place of the usual curb. Outside of this shoulder on both sides of the pavement the earth berm, 4 1/2 ft. wide, is brought to grade. On about one mile of the road, and prin-

FIG. 2—TWO TYPES OF FORMS FOR SETTING BRICK AND BUILDING CURBS

Braced about every 5 lin.ft. in either case. Templet is pulled along on top of forms to adjust sand cushion, then brick are laid and rolled. The forms are then moved back one foot and asphalt macadam laid, asphalted and rolled. Then the brick are asphalted and covered with coarse sand. Form system No. 2 has proved the better.

cipally at turn-outs and intersections, a 12 x 12-in. concrete curb has been substituted for the asphalt-macadam header.

Base Construction—Among the more interesting features of the construction is the thoroughness with which the macadam base is prepared. The subgrade trench is cut 19 ft. wide, excess dirt being pushed out for earth shoulders. The trench is then rolled until thoroughly compacted, and lined up. Upon this subgrade is placed a course of sledged limestone sized from 3 to 6 in. in such quantities as to make 5 in. after being thoroughly rolled. Upon this is placed a second course of crushed limestone sized from 2 1/2 to 3 in. in sufficient quantities to make 3 in. after filling the voids in the larger stone and being compacted. Upon this is placed enough fine material (from 3/4 in. to dust) to fill all voids in the second course. This application is broomed in dry and care is taken to fill all voids and see that any excess is uniformly distributed.

The whole is then first rolled dry, sprinkled and again rolled until as firm and tight as possible. Upon this a very fine layer (about 2 cu.yd. per 100 sq.yd.) of pure limestone dust is applied and flushed with water and rolled wet until a grout forms in front of the roller in sufficient quantities and of proper consistency to seal all cavities and honey-combed places. Brooms and, in some instances, wood floats are used to secure an absolute grouting of the entire base. After drying for about 48 hours the base is hard enough to hold up a wagon loaded with 5,000 lb. of sand, without showing a wheel mark or horseshoe print.

Wooden forms are then set up on this base 17 ft. apart leaving one foot of base outside on each side. These forms are set to the grade of the finished pavement. Enough sand is then spread to form an approximate 1-in. bedding course. This course is distributed with the templet which conforms to the surface of the finished road. The templet is pulled along on the forms and varies the depth of the bedding course enough to take out any little irregularities there may be in the base. Where variations of more than 3/4 in. show up in the base it is raised or lowered enough to allow the cushion to take up the difference. In other words, if the templet runs up on an inch and a half bump it will not ride on the forms even with no sand under it. In such cases the bump has to be cut down enough to allow the templet to ride the form and still have some bedding sand between it and the base. In

FIG. 2—MACADAM BASE BEFORE WATERBINDING WITH LIMESTONE DUST

case of a low spot too much bedding course will show and a little limestone dust has to be added, wetted and hand-tamped until the bedding course is not too deep.

After a short time the crew developed skill to the degree that it could finish the base practically to grade with the use of tees, and very little trouble was experienced thereafter when the templet was put in operation. The faithful use of the templet guarantees a finished surface as good as the average on a concrete base.

Pavement Construction—Two systems of wood forms have been used, the second proving much more practicable and probably the better. The first system, Fig. 2, consists of bracing a 2x4-in. timber on edge from the outside by means of wooden stakes driven into the dirt shoulder, the brace running from the stakes to a nailing strip cleated onto the 2x4 timber. The second system, Fig. 2, consists of laying two 2x12-in. planks flat and driving steel pins against the outside edge to hold the line. In either case the forms are set to finish grade, and it is sometimes necessary either to shim under them a little or, if there is a bump, take the base down a little. This second system gets away altogether from the use of nails and is a little more rigid. While the first cost of lumber is higher, the same plank can be used over and over again until, in the end, it really is cheaper. In either case the forms are braced every 8 ft.

After the forms have been set and the bedding course shaped the brick are set, rolled, inspected and culled. Before the brick are asphalted the forms are moved back a foot on either side, rebraced and the 1-ft. asphalt-macadam shoulder built. First, a 3-in. course of 2-in. crushed stone is tamped in and 1 gal. per square yard of asphalt is applied. This layer is then brought almost to grade with 1-in. crushed stone and again well tamped. Another gallon per square yard of asphalt is applied and the surface is brought to grade with $\frac{3}{4}$ -in. clean limestone chips, and thoroughly rolled with a five-ton tandem roller.

The brick surface is then flushed with asphalt behind the shoulder gang instead of in front. This keeps the forms from getting covered with asphalt when the brick are flushed. To keep the forms clean while pouring the shoulder they are removed after the first course of shoulder rock has been tamped into place. The dirt shoulder is thrown up into place when the forms are removed and the macadam shoulder and dirt

shoulder are rolled at the same time. In short, the shoulder and berm are built as nearly as possible in one continuous operation, the idea being to keep them completed just in front of the flush-coat gang on the brick.

After the brick have been properly filled and sanded, all excess forms and material are moved ahead. The road is opened to traffic, and a team outfit comes along bringing all earth shoulders to grade, straightening up ditches, and in general putting on all the finishing touches.

The bricks were hauled and stacked in advance of the brick-laying gang on both sides of the road where possible, and then delivered by hand to the brick setter, each man carrying four bricks at a time. The narrowness of the road made the use of conveyors of little advantage.

It took about twenty teams and ten extra men, a roller, water wagons, etc., to build 600 lin.ft. of base a day in addition to the gang engaged in crushing the rock. Eight teams and eight extra men were kept busy hauling and stacking the brick for a day's work.

FIG. 4—ROLLING BRICK AND BUILDING CURBS

Ten men carried the brick to the setter. There were two batters, three men working on the bedding course, and two teams hauling sand. Ten more men were engaged in filling the brick and constructing the asphalt-macadam shoulder. In addition, an outfit of six or seven teams was kept busy putting on the finishing touches. Work was started Feb. 15, 1922. Three crews, as outlined, were kept busy all of last summer and fall. One crew was worked in 1923.

Some of the road has now been open to traffic for about ten months and if any change can be noticed it is that it is getting smoother. It is stated by users of the road that it is as smooth as a city pavement on a concrete base. There were two connections to city pavements that settled just a trifle where, to meet the grade, a little too much sand was used in the bedding course. This was remedied by building up the base a little and cutting down the depth of the bedding course.

All work was performed under the direction of F. P. Sexton, federal highway engineer, C. H. Henning, state district engineer, and W. R. Eccles, engineer for Eastland County. The construction was in charge of P. B. Keller, superintendent of Smith Brothers, Inc., general contractors, of Dallas, Tex.

Paper Company Completes Power Plant on the Hudson

Unusual Geological Conditions of the Site—Self-loading, Multiple-Arch Dam—864-ft. Spillway—Large Concrete-Lined Canal—Reinforced-Concrete Penstocks, Scroll Cases, and Draft Tubes

FORTY THOUSAND more electric horsepower has been added to the available supply in northern New York by the completion of the International Paper Co.'s Sherman Island hydro-electric development, on the Hudson River near Glens Falls, N. Y. This plant uses the total head between the tailwater elevation of the power plant at Spier Falls and the pond of Champlain Canal Feeder Dam at Glens Falls, an average head of 65 ft. The ultimate installation will be five units of 10,000 hp. each and will utilize at full load a total flow of 7,600 sec.-ft.; but on account of the present unregulated flow of the Hudson River only four units have

been installed. Electric current is generated at 6,600 volts and transmitted at 114,000 volts to the trunk distribution system of the Adirondack Power & Light Corp.

The outstanding features of the development are the unusual geological conditions encountered and overcome. The main dam is founded on a bed of boulders and gravel, the headrace canal is excavated through fine sand, and the power house is set in a glacial flour approximating quicksand. It is located just where the Hudson River comes out of the Adirondack Mountains into the broad valley which it follows to the sea. The bottom of this valley is filled with glacial deposits of great depth. The dam is on the edge of this valley just where the steep granite rock slopes of the two peaks that flank the river dip sharply under the glacial bed. The two extremities of the dam are built on this rock and the spillway channel is excavated through it but the main portion of the dam is built on glacial deposits, a firm mass of boulders, sand and coarse gravel of unknown depth.

This formation practically precluded the idea of using a spillway dam across the river or a gravity type reservoir dam, and, as the formation of the south bank (the river here runs east) made it possible to excavate a wasteway channel through the solid rock, it was decided to use a non-overflow, multiple-arch dam across the main channel of the river and to use a gravity type section for the spillway which would be on solid rock.

From the site chosen for the dam to the upper end of the feeder dam pool the river runs in a rapids about

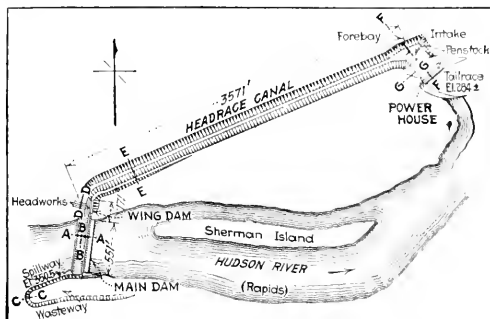

FIG. 1—GENERAL PLAN OF THE SHERMAN ISLAND DEVELOPMENT

FIG. 2—DETAILS OF THE STRUCTURES OF SHERMAN ISLAND DAM AND CANAL

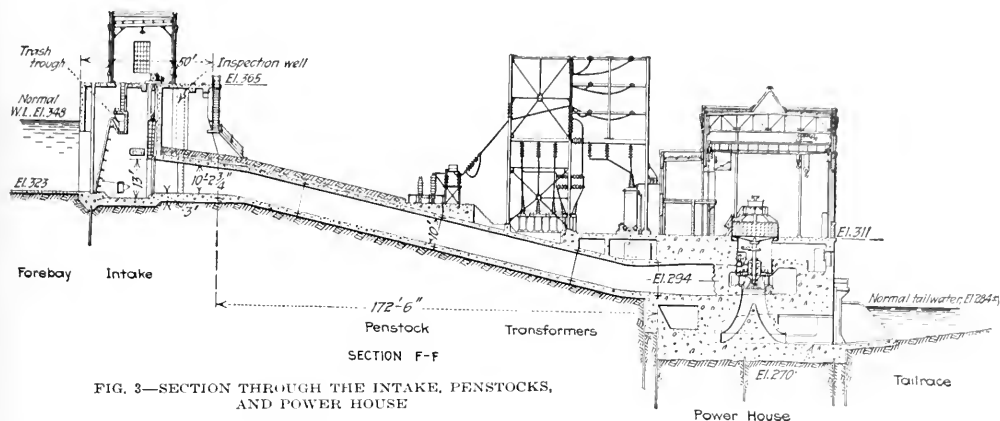

FIG. 3—SECTION THROUGH THE INTAKE, PENSTOCKS, AND POWER HOUSE

3,000 ft. long, falling 19 ft. To use this 19 ft. of head it was necessary to do one of two things, either locate the power house at the dam and excavate a long tailrace channel in the unstable material found underneath the boulder blanket of the river bed downstream from the dam, or carry a canal along in the bank of the north shore and build the power house at the upper end of the pool. The latter plan was adopted as the formation of the bank lent itself to such a development. Fig. 1 gives the general layout of the project.

Details of the Design—The main dam across the river channel is of reinforced concrete, 551 ft. long and has a maximum height of 70 ft. from the bottom of the floor to the walk. It is a multiple-arch type of dam as shown in Sections A-A and B-B, Figs. 1 and 2. The buttresses supporting the arches are placed upon a heavily reinforced floor slab which distributes the weight of the dam over the whole foundation area, thereby reducing the unit load to a safe amount. The decrease in the slope of the back from a 12:12 slope to a 5:12 slope was made in order to increase the weight of water upon the dam and, by the consequent widening of the floor, to increase the contact with the boulder bottom thus gaining more stability against sliding. As an additional precaution, the floor of the dam and the 50-ft. concrete apron below it have been covered with a layer

of sand about 20 ft. thick. This increases the weight and also serves as a protection in case of overtopping. Overtopping is, however, highly improbable as the height of the dam above the spillway is such that it would

FIG. 5—INSIDE OF COFFERDAM NO. 1 SHOWING THE CHARACTER OF THE RIVER BOTTOM

require a flood 50 per cent greater than the record flood of 1913 to overtop it.

In order to reduce the upward pressure on the dam to an average of not more than 30 per cent of the active head, a double row of Lackawanna steel sheet piling 50 ft. deep was driven along the upstream toe of the dam; and after the dam was completed the bottom of the pool

FIG. 4—GENERAL VIEW OF THE SHERMAN ISLAND DEVELOPMENT
Showing the spillway and main dam at right and top of canal lining from center to left; power house at extreme left.

immediately above the dam was filled with fine sand. Actual measurements of the pressure since the pond was filled show that the pressure is well below the prescribed limit.

The thickness of the arch ring in the main dam is notable. It is only 18 in. in the upper section and 24 in. in the lower section. These shallow thicknesses were used in order to increase the elasticity of the arches and to reduce to a minimum the stresses due to shrinkage and temperature changes.

The spillway is all on solid rock and is of mass concrete of gravity section. It is horseshoe shape in plan to give a weir length of 864 ft., the length required to take a flood of 100,000 sec.-ft., with a margin of 2 ft.

them as simple as possible and to introduce the minimum amount of obstruction in the channel by making it possible to raise the gates entirely out of the channel when not in use. They are of reinforced concrete with angle irons to protect the edges and make tight fitting joints. Each of the ten gates is made in three sections 7 ft. x 10 ft. 2 in. and 18 in. thick, fastened together by manganese bronze links and pins. The link between the middle and the upper section is slotted to provide a 14-in. opening for filling the canal and for supporting the gate in its raised position. These gates are raised and lowered by a 20-ton electric hoist mounted on a craneway running the full length of the headgate structure. The gage well and the pump well are located in

FIG. 6—DETAILS OF THE WORK DURING CONSTRUCTION

for the turbine draft tubes. (4) Temporary roller gates for closing the last openings in the main dam.

below the top of the main dam. The wasteway channel was so designed that under no circumstances would the weir be submerged. There are seven sluiceways through a bulkhead section built into the spillway for use in case it is necessary to partially empty the pond.

At the north end of the dam is a wing dam 171 ft. long of gravity section built on solid rock. It closes the gap between the main dam and the south embankment of the canal and forms the east abutment of the headworks. The west headworks abutment is against the side of the short rock channel that forms the upper end of the headrace canal. The headworks structure is of reinforced concrete built on solid rock and is designed as a dam sustaining a head of 35 ft. It is shown in detail in Fig. 2. The novel feature of this structure is the design of the gates. In view of the fact that they need to be lowered into place only when it is necessary to clean or repair the canal and need not be quick operating when refilling the canal, it was decided to make

this structure as is a log gate for driving timber through the canal.

The headrace canal, with the exception of the first hundred feet, is excavated through a glacial deposit which ranges from coarse gravel to quicksand, most of it through a moderately fine sand. For this reason all but the short rock section at the upper end is lined with concrete up to a level of six feet above the spillway elevation. Above this level the slope is rippedraped to protect it against scour during the short duration of floods which might go above it. The forebay is lined with concrete to this higher level on account of the surge. The details of the canal are shown in Fig. 2. The slab is reinforced with expanded metal mesh to concentrate the expansion in the expansion joints. It is built up in 21-ft. sections, with construction joints at the center and sides of the floor and 40 ft. up the slope where the thickness is increased from 6 to 9 inches. Each joint is closed with a 6-in. copper expansion strip.

FIG. 7—THE CANAL AND HEADGATES

Top of main dam can be seen beyond headgates; concrete mixing plant under temporary trestle at center of the canal.

This design was used on account of the need for greater flexibility in the lining of the canal and it was hoped that there would be very little loss through the joints, but during construction a stratum of water-bearing sand was encountered along the inland side of the canal which made it necessary to leave openings through the lining to take care of the water. After the lining was completed an attempt was made to close up these openings by grouting, but it was not entirely successful and after the canal was filled it was found that there was a loss of about 5 sec.-ft. As the machinery in the power house was not ready for operations it was decided to empty the canal to make observations of the lining. The gates were opened and the canal emptied in about 4 hours. After the water was out of the canal a section of the lining about 1,000 ft. in length on the inland side was found to be damaged in places and other places pushed out into the canal. This was undoubtedly caused by a hydrostatic pressure built up between an impervious layer and the canal lining. Repairs were made by replacing the damaged portion of the lining, adding concrete in heavy steps along this 1,000-ft. damaged section, together with a single step along the toe of the slab at the river side, and concrete struts from side to side laid on the bottom. In addition to this numerous weepers were placed in the bottom of the canal. These consisted of 4-in. pipes carrying simple lift valves at the top. Furthermore, all

the construction joints throughout the canal were carefully filled with gunite. Since these repairs were made the canal has been refilled and no abnormal leakage has appeared.

The forebay dam is built on sand. It is of reinforced concrete with a heavy bottom slab and 3-ft. and 3 ft. 6-in. buttresses at 10 ft. face to face. It is provided with a steel sheet pile cutoff 15 ft. deep. There is, however, little possibility of any uplift on this structure as the lining of the canal is connected to it by watertight joints similar to those used in other parts of the canal. Moreover, the ground drops away in front of the dam insuring proper drainage. The intake works are made an integral part of the central portion of the forebay dam as shown in section in Fig. 3. There is a log-way at the east end which runs down to the river below the power house. An interesting feature of the intake is the trash trough along the top of the trash racks shown in Section F-F. It runs the full length of the structure and empties into the log-way and is provided with a 12-in. valve at the upper end for flushing it out.

Fifteen reinforced-concrete penstocks, built in groups of three, have their upper ends in the 10-ft. spaces between the buttresses. They are closed with Broome caterpillar sluice gates operated by electric hoists situated in the gate house on top of the dam. As an emergency measure stop-log grooves have been cast in the concrete in front of the trash racks.

FIG. 8—UPSTREAM SIDE OF THE DAM AND SPILLWAY

Showing, left to right, cement shed and stone stockpile, mixing plant, part of the headgates, main dam and wasteway channel.

FIG. 9—BUTTRESS FORMS ASSEMBLED READY TO BE SENT OUT TO THE DAM

The penstocks are 10 ft. x 10 ft. 8 in. in section and 172 ft. long. They are heavily reinforced and have a minimum wall thickness of 18 in. Each group of three serves one turbine as shown in section in Fig. 2. As the whole penstock structure is built on sand, some of which is soft, it is divided up into separate sections by longitudinal and transverse joints. Longitudinal joints are made between the groups of three, and the five transverse joints are closed with lead strips, and in addition are calked with tar and oakum on the inside. The inner surface is waterproofed with an iron compound.

The Power House—Test shafts and borings made at the power house site indicated that quicksand underlay the whole area. The problem of confining this sand was solved by dividing the foundation area up into ten box sections by steel sheet piling driven to 25 ft. below subgrade. These sections act as sand columns transmitting the load to a safe depth. To take care of the unbalanced horizontal load and to prevent squeezing out of the material in front of the power house the tailrace apron was carried out across the light sand bed about fifty feet to a point where gravel was encountered in the river bed. Heavy buttresses were carried up from this apron to the side of the power house. Observations were made on the power house foundation during construction to check the settlement. It was progressive during the pouring of the great mass of concrete in the foundation and draft tube blocks but since these were completed there has been no settlement. Fig. 3 shows the power house in section. The ultimate installation will be five 10,000-hp. vertical turbines. The scroll cases and the Moody spreading draft tubes are of concrete.

The superstructure of the power house is of brick and steel with a gypsum roof. A transverse traveling crane of 50 tons capacity serves the whole generator floor and reaches the standard-gage railway track where it centers the west end of the building.

Construction—The construction work started in No-

vember, 1920, with the grading and laying of a 6½-mile railroad from Glens Falls to the camp site. Portable and semi-portable frame buildings were put up for the main camp, and a group of cottages which will later be used for the permanent employees were erected for the use of the construction staff. The camp was provided with a septic sewage system and with a duplicate water supply, a drinking water supply from a small reservoir in the hills back of the camp, and a general supply pumped from the river to an elevated tank. Electric current for lighting and power was brought to the site by a 6-mile transmission line from Glens Falls.

The construction camp was equipped with a machine and blacksmith shop, air compressors, sawmill, wood-working shop, and storehouses. These were all located along the standard-gage railway tracks. A 1,400-ft. cableway was built from a central point in the camp to a similar high point on the south shore, parallel to and above the center line of the main dam.

In the spring of 1921 two bridges with stone-filled crib piers and I-beam stringers were built across the river, a double-track structure above the dam site and a single track one below. Cofferdam No. 1, 350 ft. long by 250 ft. wide, at the north side of the river was driven outside the line of the bridge. The sides of the cofferdam were constructed of a single row of Lackawanna steel sheet piling, supported by three rows of wales which in turn were held by the crib pier and the intermediate struts.

The central concrete mixing plant and the rock-crushing plant were located on a natural terrace about 25 ft. above normal water level on the north river shore above

FIG. 10—DETAILS OF THE BUTTRESSES Showing method of framing for the arch rings.

FIG. 11—THE FOREBAY DAM, PENSTOCKS AND POWER HOUSE
Showing the formwork for the penstocks.

the dam site. Rock for the crushing plant was brought from the excavation for the spillway channel on the south shore. The immediate needs of the mixing plant were supplied by one belt conveyor, and a second conveyor delivered the excess to a stock pile up at track level in the camp. Pit-run sand from the canal cut was supplied to the mixer from the high-level tracks. Cement was brought in bulk from the Glens Falls Cement Co. and was delivered in four hopper-bottom cars specially roofed for that purpose. This cement was dumped into large storage bins built under a spur of the high-level tracks and was fed to the mixing plant bins by a belt conveyor. The central mixing plant had two one-yard mixers equipped with Johnson proportioners for proportioning by weight. All the equipment, crushers, belt conveyors, screens, mixers, air compressors and large pumps were electrically driven. The concrete for the portion of the dam near the mixing plant was spouted from a tower at the mixer but for the greater part of the structure it was deposited from buckets moved by flat cars or from a spouting plant built in a gantry traveler and supplied by buckets carried out on the cableway.

Most of the concrete formwork was done at the wood-working shop in the camp on the high level and was sent out to the dam on the cableway. All reinforcing material was distributed in the same way from a storage yard located under the cableway along one of the tracks in the camp.

During construction of the north half of the dam openings were left between the buttresses at the upstream side of the dam as shown in Section A-A, Fig.

2. The idea of these openings was that as soon as the concreting of this half had been carried above high-water level the cofferdam could be cut and the river allowed to flow through these openings while the south half of the river was shut off by cofferdam No. 2 after the flood period of 1922. Four similar openings were left in the south half of the dam when it was built and these openings were equipped with temporary roller gates. After the main dam and the spillway had been completed, and during the low water of the fall and winter of 1922-23, the temporary openings in the north half were first closed with stop logs and then concreted up. Then when the dam was in shape to start filling the four roller gates were closed and calked from the downstream side. When everything appeared to be holding satisfactorily under the rising water in the pond these openings were concreted up by means of large steel pipes carried up above the level of the water in the pond.

The headrace canal, with the exception of a short section at the headgates, was all in sand and gravel. It was excavated by dragline and steam shovels approximately to grade and was then carefully finished off to subgrade by hand. This subgrade was used for the bottom of the forms in pouring the lining. The lining was poured in alternate 21-ft. sections, the bottom first then the lower 6-in. slab on the slopes, followed by the upper 9-in. slabs. For pouring the slabs 6-in. or 9-in. stringers were laid up the slope to make the side forms and 26-in. portable panels, held in place by concrete weights, were used for surface forms. The expanded mesh reinforcing was laid on the slopes before pouring started to provide a footing in the soft sand for the

FIG. 12—DOWNSTREAM FACE OF THE COMPLETED DAM
Showing the 20-ft. fill on the floor and apron of the channel section.

workmen. As the concrete was poured this mesh was pulled up into place with hooks.

Concrete for the canal lining was mixed in a plant suspended between the bents of a trestle which crossed the canal. From this 1-cu.yd. mixer the concrete was run directly into 1-cu.yd. buckets on flat cars operated on a double-track railroad laid in the bottom of the canal. Locomotive cranes distributed these buckets to the concreting gangs and also placed form panels.

Cement, sand, and stone for the canal mixing plant were dumped from the deck of the trestle to the bins underneath the track. Latterly, when the main dam was finished and the site of the central mixing plant was submerged, a tower was erected at the side of the canal plant and concrete was mixed there and delivered to cars on the deck of the trestle.

Concrete for the power house and the major part of the forebay dam was handled by train in 2-yd. side-dumping buckets from the central mixing plant to a distributing tower, on a high point above the power house and forebay dam. Concrete for the penstocks was mixed in a 1-cu.yd. plant built on a high point at the end of the forebay dam. All concrete was proportioned by weight. The proportions were changed constantly, both on account of the four classes of concrete used and on account of the variations in the pit run of sand and crusher run. Concrete for the massive work was mixed substantially in the proportions of 1:3:6, for the lighter work 1:3:5, and for the light reinforced parts 1:2:4. The canal mix was made about 1:3:2 on account of the difficulty of working the concrete into the 6-in. forms.

Great care was used in the control of the mixing water to see that there was no excess. Samples were taken from the concrete at regular intervals and cast into 10-in. cylinders. These cylinders were cured and then tested at the Rensselaer Polytechnic Institute.

For winter concrete work the sand and stone bins were equipped with steam coils and the water was heated. By this means concrete was usually delivered at the forms around 50 deg., the early morning batches being as high as 90 degrees. Temperature tests were taken on all cold days and a check was kept on the temperature of the concrete in place for periods extending over weeks in some cases. All exposed work was protected with hay and paper.

Generally the temperatures were higher on the day immediately following placing and then fell off slowly. One large section of mass concrete in the wing dam poured on January 21 never registered an internal temperature below 34 throughout the winter.

The turbines were designed and built by Wm. Cramp & Sons, and the electrical equipment by the General Electric Co.

The general design was made by A. H. White, chief engineer of the International Paper Co. H. deB. Parsons was consulting engineer and designed the main dam. The structural details were worked out by E. E. Halmos, designing engineer, and S. A. Thoresen of the firm of Parsons, Klapp, Brinckerhoff & Douglas. The construction work was done by the Parklap Construction Corp., under the direction of W. J. Douglas, president, and E. E. Halmos. The field staff consisted of L. A. Little, manager, W. F. Barnes, general superintendent, and G. Miller, supervising field engineer. H. M. Hale was resident engineer for the International Paper Co.

The Truth About Civil Engineering

A Talk Broadcast from W. J. Z. New York City, by Frank C. Wight, Managing Editor, Engineering News-Record. [Printed by Request]

IN THESE days of the silver screen there is no need to tell anyone what a civil engineer is. Every movie fan knows that he is that handsome, though rugged, chap in the nicely pressed khaki breeches and knee boots who bosses a thousand or so roughnecks building a dam in the eucalyptus covered hills back of Los Angeles. His professional activities consist in a few moments' studious attention to a blueprint or two, a short glimpse through some kind of a surveyor's instrument and some hail-fellow-well-met directions to a couple of men working near a derrick. The rest of his time is spent in bashful devotion to the daughter of the New York banker who is financing the dam. Along about the fifth reel the slick-haired lounge lizard who has pursued said daughter all the way from New York, manages somehow to get a nasty-looking bomb over the side of the several hundred thousand yards of concrete that make up the dam, but before the fuse gets in its dirty work to discredit our hero, that gentleman—his pants still neatly pressed—dives overboard, grabs the bomb, swims out with it and hurls it toward a road over which, unknown to him, the villain in a speeding auto is kidnapping the heroine. The bomb explodes, the automobile dives into the crater, the villain dies in such fashion as the censor will permit and the heroine somehow tumbles into the arms of the civil engineer. Fade-out of civil engineer and banker's daughter against background of dam, derricks, and surveying instruments.

This isn't confined entirely to the movies. The civil engineer is in danger of becoming characterized by the artists, both pictorial and fictional, as the great romantic—the successor of the cowboy and the soldier, the exponent of the wide open spaces, the two-fisted man who gets things done but always in the romantic manner, who moves gaily through a picturesque, an unusual, an adventurous life. It is far from a joke to say that the greater number of the recruits to the profession are drawn there by just this appeal.

In marked contrast to this idealized picture of a civil engineer is the too prevalent viewpoint of the big business man, the politician and the banker, the men who handle the strings of the purse into which the civil engineer must dip for the wherewithal to carry on his work. These men are prone to consider the engineer as a sort of higher class journeyman—a mathematician, a surveyor, a draftsman—who deals only with material things; a good enough sort of expert to plan the transformation of steel and concrete and earth and rock into the tunnels, and buildings, and bridges and water-works the world must use, but after all a mechanic with no sense of men or business or beauty. He is necessary to the world, of course, but not one who can ever rise very high in its direction.

Of these two conceptions of the civil engineer, the latter is by far the more offensive. No special harm is done the profession by painting it with an over-romantic brush. Boys who are led to become civil engineers by the adventurous appeal can find sufficient adventure if their youthful ambition that way persists. And if the glamour of adventure wears away, as it does with most, there remains for them that solid work which makes up most of the profession's activities. But the other viewpoint is offensive to civil engineers because it is wrong and because it constantly works to reduce the effectiveness of a profession which, considered properly, could do so much more to improve the conduct of the world's business. It is as a plea for the consideration of the civil engineer as something more than a servant of business and government that this brief talk is intended.

Engineering, in the classic phrase of one of the oldest professional societies, is the directing of the powers of nature to the use of man. That is pretty broad defining and does not help much in an interpretation of the civil engineer. Another and less dignified definition is that an

engineer is one who can do for one dollar what any fool can do for two. But that merely explains motive and does not describe activities. It will help to an exact appreciation of what a civil engineer is perhaps to say that he is one who conceives and executes the structures necessary to man and the services necessary to his health and convenience. Bearing in mind, then, the important dual capacity of both conceiving and executing—he is responsible for bridges and buildings, for tunnels, for roads, railways, canals, for the control and regulation of rivers both as protection against floods and as preservation for power or water supply, be it for drinking water or irrigation, for draining wet lands and for watering those that are over dry, for laying out and maintaining the streets of our cities, for bringing water to those cities and for taking away their refuse.

These are his practical activities; he is, it will be seen, the great satisfier of the physical and material needs of man. For that, however, the civil engineer takes no undue credit for he realizes that civilization is a complicated organism, that each of the many functions has equal importance. The civil engineer is no more necessary than the doctor, the merchant or the farmer for without any of them the organism would either cease to function or at best function very imperfectly.

The civil engineer does, however, take credit for the manner in which he goes about satisfying the needs of humanity. He believes that the underlying principle of his creed and the way he practices that creed entitle him to a better appreciation of his wider capabilities, not because such appreciation would hasten his own advancement but because it would react to the good of everyone.

Honesty and economy are the fundamentals of this creed. The engineer is not vainglorious when he says that he is honest; he is not thanking God that he is not as other men. It is merely one way of expressing the scientific spirit that must govern engineering. From his earliest school days he is taught to pursue the facts and nothing but the facts. He must know the truth and he must utilize only the truth. Those material things he deals with are not susceptible to argument; they will act only according to immutable law. Added to this basic necessity for knowing the facts he must have the faculty of moving from fact to further fact by reasonable processes of thought so that the final result will be as near in accordance to the truth as the frailty of man's mental processes will permit.

It is submitted that the type of mind which is insatiable in its desire to learn the truth and then trained to apply that truth to beneficial ends is one which the world can well use in solving many of the problems not ordinarily associated with civil engineering.

The second part of the engineer's creed is equally important—economy. To do a thing as well as it needs to be done for the least cost consistent with that end. Not to do it cheaply, for that would not be doing it as well as it need be; not to spend money in needless embellishment for that would be doing it better than it need be, but to weigh the necessities and then exactly to satisfy them—this is the engineering ideal. Is not such an ideal needed in our government? Is it not needed in our industries? Is not the man who truly serves such an ideal better fitted to conduct a city than the much vaunted business man whose ideal is profit, whose whole training is based on a judicious assumption of risk and who is satisfied if one successful venture more than makes up the losses from half a dozen unsuccessful ones?

And so we civil engineers make a plea to the rest of you. We are not khaki clad romantics—though some of us do wear khaki once in a while and probably all of us have as much of a romantic and adventurous streak as the next one. We are not those chaps you see out on the road once in a while peeping through a funny looking telescope set up on three legs. Surveying is a necessary but rather elementary part of engineering, though every artist who paints a picture of an engineer sticks him up alongside a thing he fondly considers to be a surveying instrument. We are not rank materialists who are con-

cerned only with the putting together of so much steel and concrete into a usable structure. We are a group of men reared in a stern school of adherence to facts who are touched now and then with the divine spark of imagination which gives you a Brooklyn Bridge or a Catskill Aqueduct. Because of the very nature of that with which we deal we must see clearly if we are to succeed. Because no material thing can be completed without human aid, we must understand our fellow man. Because only those things that pay can be built in this material world, we must appreciate the value of the dollar and what it can be made to do. We submit that here is a combination of qualities—qualities, be it noted, of a profession and not necessarily always combined in each member of that profession—which the world has not adequately utilized.

Meanwhile, do not think of civil engineers as mathematicians who possibly make mathematics do things or, at the other end of the scale, as mechanics who have not organized in labor unions. Think of them as practical scientists, as men who come in daily contact with three things, (1) natural forces, (2) man and (3) money. To co-ordinate those three so that they jointly can do the best work is the real job of the engineer.

A Substantial Bridge Railing

WHAT appears like a concrete truss to carry substantial loads in the view herewith, is merely a hand-railing surmounting a concrete arch bridge in a Montreal park. This railing appears capable of holding a fairly heavy vehicle from going overside. Substantial railing construction on bridges and viaducts, as well

HEAVY RAIL OF A PARK BRIDGE

as on road fills, has been found desirable by many state highway departments and city bridge and street bureaus, but construction as heavy as that shown here is not common.

Seven Years' Federal Aid Road Work

During the period of federal aid in highway construction, from July 11, 1916, to June 30, 1923, there have been completed 23,297 miles of roads at a final cost of \$407,704,641 according to statistics announced by the Bureau of Public Roads. There were under construction on June 30, 14,771 miles of federal-aid highway, with an estimated final cost of \$274,080,168. construction on that date being 53 per cent completed. The average cost of all types of the 23,297 miles of highway was \$17,500 per mile. On a general average, the figures varying with different types and localities, the cost of constructing has been divided: grading, 22 per cent; surfacing, 53 per cent; structures, 16 per cent; shoulders, 1 per cent, and miscellaneous, 3 per cent.

Design of Earthquake-Resistant Buildings in Japan

Details Provide Unusual Strength at Column Joints
—Heavy Sway Bracing Used—Struts
Between Foundation Piers

SUPPLEMENTING the notes on structural design of steel-frame buildings in Japan, published in last week's issue, page 434, there are presented herewith typical structural details of the Japan Oil Co. building in Tokyo. This is a seven-story steel-frame structure occupying a ground area of 150x156 ft. and was constructed by the George A. Fuller Co. of the Orient, a Japanese subsidiary of the New York organization of the same name, from designs prepared by Purdy & Henderson, consulting engineers, of New York City, in collaboration with Japanese designers. The details in the accompanying drawings have been selected to indicate the methods employed to make the structure secure against damage by earthquake shocks. These details cover a typical spandrel girder with the heavy knee-bracing of double 6-in. channels between column and girder, heavy column bases with clip angles to engage the reinforcement in the concrete struts which extend in both directions between all pairs of pile-supported concrete piers, the framing plan of a typical panel of the building, and, of particular interest, a typical column splice made up of layers of plates requiring 416 rivets. There are also shown details of the interior girder beam and column connections.

Taken in conjunction with last week's article, the drawings are largely self-explanatory. Of particular interest to American designers is the heavy column splice which places no value on the bearing of one column length upon the other. The assumed loading on column No. 58 at the second floor, the one shown in the accompanying drawing, is 640,000 lb. The following explanatory note appears on the designer's blueprint of the column splices: "Area of splice plates to equal area of column above and sufficient rivets provided to develop the plates at 16,000 lb. per square inch. Following rivet values to be used: Shop rivets, $\frac{7}{8}$ -in. at 7,200 lb., and $\frac{3}{4}$ -in. rivets at 5,300 lb.; field rivets, $\frac{7}{8}$ -in. at 6,000 lb., and $\frac{3}{4}$ -in. rivets at 4,500 lb. Where filler plates are required, the number of tack rivets to be equal to 20 per cent of shop rivets. Not less than two lines or more than four lines of tack rivets to be used except at roof splice."

It will be noted that both web and seat connections are provided between girders and columns.

The preliminary indications that all of the three large steel structures in Tokyo—the Japan Oil, the Maranouchi, and the Nippon Yusen Kaisha office buildings—withstanding the earthquake of Sept. 1 are confirmed by the following statement issued Sept. 13 by the U. S. Department of Commerce: "American steel and concrete buildings in Tokyo and Yokohama withstood the earthquake shock and are in good condition, according to a cable from Assistant Trade Commissioner G. C. Howard at Kobe. Officials of the Department of Commerce expressed gratification over the first practical demonstration of the effectiveness of the new so-called earthquake-proof factories and office buildings which have been constructed in the past three years. The fact that this construction has proved earthquake-proof is likely to influence adoption of this type in the future."

TO WITHSTAND SEISMIC SHOCK

Structural details of Japan Oil Co. Building in Tokyo, indicating precautions taken to insure strength by heavy sway-bracing, and unusual column splice.

Garbage Piggery and Residue Drying Cheapest for Buffalo

H. P. Eddy Reports on Bids Advising Against Incineration and Recommending Either (1) Reduction or (2) Hog Feeding with Residue Driers of One-Half Piggery Capacity

BASED UPON a detailed analysis and comparison of bids for various single and combined processes of garbage disposal obtained last year by the city of Buffalo but not yet acted upon, Metcalf & Eddy, consulting engineers, Boston, Mass., have advised against incineration, either singly or to treat piggery wastes, and have recommended that a choice be made between garbage-reduction by the Cobwell-Merz process and a piggery supplemented by a garbage-and-manure drying plant.

Bids Were On Open Specifications—The bids considered were based on the bidder's own plans for plant and machinery only and could not be compared for purposes of the report until after elaborate estimates had been made to cover various omitted items necessary for working installations. After this had been done, and the schemes offered had been reduced to two, it was found that there was but little difference in capital cost between reduction alone and a piggery combined with a plant to dry the uneaten garbage and the piggery manure, but that the cost per ton for reducing 40,000 tons of green garbage a year would be some 40 per cent more than for feeding the same amount of garbage to hogs and disposing of the residue and the hog manure by drying. Reduction would yield grease and fertilizer base. The other plan would produce fat hogs and fertilizer base. It should be understood that of the three types of incinerators formally bid on only one had ever been operated in this country, and that on a small scale; none, the report states, had been used for garbage unmixed with combustible waste; and none had ever consumed garbage-feeding wastes. The final recommendation of the report was that the city authorities decide between (1) reduction alone and (2) hog feeding and residue drying and then have a plant of the type chosen properly designed and invite bids on the city's designs.

The bids in question were received July 25, 1922, and transmitted to the Buffalo Commission Council on Oct. 18, 1922, by William F. Schwartz, street commissioner of Buffalo, with a request that he be authorized to engage H. P. Eddy, of Metcalf & Eddy, to report on the bids. On Oct. 25, Mr. Eddy was authorized to make such a report, which was sent to Mr. Schwartz on March 10, 1923. The latter transmitted the report to the City Commission April 18, with the request that the Commission choose one of Mr. Eddy's alternative plans, Mr. Schwartz himself recommending the combined piggery and residue-drying plant as the least expensive of the two. The Buffalo Council has not yet acted on the recommendation.

Reduction Formerly Used at Buffalo—For many years the garbage of Buffalo was disposed of by reduction under various contracts. The latest of these was with the International Agricultural Corp., known locally as the Buffalo Fertilizer Co., at a plant located at Sloan, N. Y. On renewal of a contract with this company that expired July 31, 1916, the contract price was reduced from \$1.25 to \$1 per ton, and after the renewed contract expired three years later the same

concern continued to dispose of the garbage until Oct. 1, 1919, but on a cost plus 10 per cent basis. During these two months the city delivered 3,714 tons of garbage to the company and paid it \$13,515 or \$3.64 a ton for its services, the amount being certified to by public accountants.

Change to Hog Feeding—Meanwhile a five-year contract was let for disposal by feeding to hogs, the price paid to the city to be 50c. a ton of garbage delivered to the contractor as a minimum, with maximum prices per ton 6, 7 and 8 times the price of live hogs, as the quantities of garbage increased. This contract was let to Dr. T. B. Huff, who organized the Huff Feeding Corp. This company, Mr. Schwartz states in his letter transmitting Mr. Eddy's report to the Buffalo Council, leased a site on the river road and spent \$247,000 for hogs, buildings, water and sewer pipes. Mr. Schwartz adds that the company never had hogs enough to dispose of the garbage; that its sewage-works were inadequate; that large quantities of garbage remained uneaten, and that this material, together with hog offal, dumped on fields around the piggery, caused bad odors, swarms of flies, and a nuisance that led to local complaints and then to orders from the State Department of Health to abate the nuisance.

City Took Over Piggery—The outcome of the conditions just outlined was that the city took over the plant on Oct. 2, 1921, subsequently paying \$45,000 for liens and claims against the Huff Feeding Corp. and \$72,157 to the owner of 2,810 hogs at the piggery. From Oct. 1, 1919, to April 1, 1922, Mr. Schwartz states, about 100,000 tons of garbage were disposed of at the piggery, at a profit of about \$15,000 to the city (methods of figuring profit not stated).

Bids Invited and Received—The lease of the piggery site, which expires Oct. 1, 1924, was such that the city did not feel warranted in spending money to improve the plant. Accordingly, Mr. Schwartz was authorized by the council to advertise for bids for (1) garbage disposal sites; (2) "machinery and equipment" to dispose of 200 tons of garbage daily by either incineration or reduction; (3) "machinery and equipment" as in (2) but of a capacity of 50 tons or more daily, to handle uneaten garbage, etc, and manure from a piggery, the latter to be provided by the city. Under (2) and (3) the bidders were to submit "detailed plans and specifications showing their methods of incineration or reduction, * * * the cost of operation per ton, the commercial value of the residue, the names of the cities where similar plants are being operated, and a guaranty that no obnoxious gases or odors will be created through operation." The site specifications called for land within 15 miles of Buffalo, adjoining a railroad, the areas to be not less than ten acres for either an incineration or a reduction plant and from 200 to 600 acres for a piggery combined with a smaller reduction or incineration plant.

Four Proposals Found Informal—Four of the nine proposals were thrown out by Mr. Eddy as not complying with the city's specifications. Of the five remaining bidders, three proposed incineration, one drying to pro-

duce fertilizer material, and one reduction—for grease and fertilizer. Although Mr. Eddy worked out comparative costs for each of the five bidders and their ten bids yet in his conclusions he advises against incineration for Buffalo garbage, for reasons stated below. He also strongly recommends that the city decide whether it wants a reduction plant alone or one to dispose of the residue from a piggery and then have complete designs made for the kind of plant chosen and invite bids accordingly.

Five Bids Considered—The five bids studied by Mr. Eddy may be summarized as follows, taking the three bids for incinerators first, then the one for drying and finally that for reduction:

Vulcan Incinerator Co.—Top hand-fed incinerating units, circular in plan, about 12 ft. in diameter, with a two-story firebox projecting at the front so as to give a fire above and below the garbage; and a combustion chamber and dust collector projecting at the rear. Forced draft is provided for the extra grates and for the incinerating chamber, forced-draft air to be preheated. No power production from waste heat is proposed. There is no mechanical apparatus for handling either the garbage, clinker, ashes or dust. The total operating cost of properly operating a 200-ton-per-day plant is given in the bid as not above an average of \$1 per ton of garbage incinerated. Vulcan incinerators are reported as in operation at Ardmore, Durand and Okmulgee, Okla., these places having had populations of 7,340, 14,187 and 17,430 in 1920.

Balmer Corp.—Top hand-fed units of three furnaces, with induced and forced draft of preheated air, the hot gases passing around baffle walls in a gas-settling and combustion chamber. Clinker and ash are lifted by elevators to elevated storage bins for removal by trucks. No power production from waste heat is proposed. Balmer plants are reported in operation with capacities from 5 to 1,000 tons in 24 hr.; one of 1,000-ton total capacity in Buenos Aires, a 300-ton plant at Montevideo and a dozen smaller ones in the Argentine.

George W. Goethals & Co., Inc.—A "universal incinerator, Didier system" is proposed in which the garbage is shredded, stored in bins, fed to charging cans and incinerated in retorts under preheated force draft. The gases from each battery of retorts pass through a portion of a combustion and settling chamber, the upper part of a water-tube boiler and a boiler superheater, the lower part of the water-tube boiler, and thence through the second compartment of the combustion chamber, in which there is a heater for the air blast. Two Didier plants have been operated: a 50-ton plant at Davos, Switzerland, a place of 15,000 population; and a 100-ton plant for Weisbaden, Germany. The smaller plant is in use but the larger one was shut down in 1919 on account of lack of funds.

C. H. A. Wannenwetsch & Co.—This bid is for converting garbage to a fertilizer base, by grinding, wringing or pressing, and drying after pre-sorting out foreign material by hand on a belt, with salvage of rags and other salable substances, and after pieces of iron and steel have been removed by passing the sorted garbage through magnetic rolls. The dryers are vertical steam-jacketed cylinders provided with stirring paddles on a vertical shaft. Plants of this kind "have been and are now operated" at industrial works to dry animal tankage, and "in one case piggery refuse was success-

fully dried under our observation." The report also states that such a plant is now being used to dry "garbage at the Buffalo Municipal Hospital."

C. O. Bartlett & Snow Co.—The "Cobwell-Merz process" for recovery of grease and tankage was proposed, making use of disintegrators, dehydrators, reducers (heat and solvent), with screens and magnetic separators for dried tankage and multiwhirl condensers, coolers and separators for grease. Besides installation cost a 6 per cent royalty fee on gross income from products during the remaining life of the patent (granted in 1918) would be paid by city. The process, at the time of the bid, was in use in New Bedford, Mass., Rochester, and Syracuse, N. Y., and had been used at Los Angeles, Calif. [and for a short time in New York City.—EDITOR].

Amount of Garbage—During the year ending with September, 1922, the deliveries of garbage to the piggery totalled 20,762 tons. It is estimated that this came from only 60 per cent of the population so that with complete collection there would have been 34,600 tons for disposal, or an average of 95 tons a day for every day in the year, or 115 tons per collection day (300 such days in a year). Based on the maximum collection day (112.8 tons) the daily maximum with full collection would be 188 tons. In percentages of average collection day the figures are: Maximum day, 169; maximum week, 150; maximum five consecutive weeks, 131.

The per capita production for the year 1921-22 [(Collection ÷ 60) × 100] was 132 lb. Mr. Eddy assumes for 1923 an average production of 150 lb. per capita for a population of 533,000, which would give 40,000 tons for the year and average 133½ tons per collection day. Adding 50 per cent the maximum collection day would give 200 tons—which was the basis for the bids.

Meager Data; Bids Not Comparable—The meagerness of the information as to the "character and sufficiency of the mechanical devices" proposed by the bidders and the fact that the bids are "not strictly comparable" because of the differences in design of the plants proposed made it necessary for Mr. Eddy to estimate the cost of various plants complete, together with their operating expense and revenues, annual charges and net annual costs in order to make the bids comparable; also to make estimates for 100-ton plants in place of the 50-ton plant bids, since Mr. Eddy concluded that to dispose of piggery wastes 100-ton plants would be required.

Tabular Data—Table I herewith, which is a combination of several tables and parts of tables in Mr. Eddy's report, reduces to a comparative basis the bids for the 200-ton plants for disposing of all the garbage, and the bids for the 50-ton plants for piggery wastes only (compared as to first cost only, since Mr. Eddy considers a 50-ton plant for this work only half large enough). Table I also gives a summary of the comparative estimates for 100-ton plants to handle piggery wastes only.

Incinerator Bids Dropped—After considering these figures and related matters Mr. Eddy dropped from further consideration the three incinerator bids. His reasons for doing this are:

Conclusions: Incineration of garbage containing about 75 per cent moisture without the addition of fuel and without creating offensive odors with any of the incinerators bid upon appears to us to be impracticable.

TABLE I—COMPARISON OF BIDS FOR VARIOUS METHODS OF DISPOSAL OF THE GARBAGE OF BUFFALO

	Construction Cost: 200-Ton Plant (Excluding Land)				
	Vulcan Incinerator Co.	Babier Corp.	George W. Goethals Corp.	C. H. A. Wannewetsch & Co.	C. O. Bartlett & Snow Co.
Proposal price, \$100,000	\$90,700	\$100,000	\$109,400	\$218,000	\$292,000
Metcalf & Eddy estimate of items not covered by proposal ¹	197,200	64,400	269,000	273,700	283,400
Total	\$287,900	\$164,400	\$578,400	\$491,700	\$575,400
Add for omissions 5 per cent.	14,400	18,200	28,900	24,600	28,800
Total	\$302,300	\$182,600	\$607,300	\$516,300	\$604,200
Add for engineering and contingencies 15 per cent.	45,300	57,400	91,100	77,400	90,600
Total (revised estimate)	\$347,600	\$240,000	\$698,400	\$593,700	\$694,800
Total, per ton of capacity ²	\$1,738	\$1,200	\$3,492	\$2,969	\$3,474
Returns: 200-Ton Plant—1331 Tons per Day					
Supervision and labor (8-hr. day)	\$35,600	\$34,400	\$39,900	\$71,100	\$78,000
Fuel, coal at \$5.50 per ton	17,600	17,600	17,600	26,400	55,000
Solvent at \$0.16 per gal., 3 gal. per ton					19,200
Water supply at 150 per cent. of city rates	400	400	2,800	17,200	400
Light at \$0.10 per kw.-hr.	2,100	1,100		3,800	
Power at \$0.01 per kw.-hr.	2,000	2,000		10,000	
Miscellaneous supplies and expense at \$0.15 per ton	6,000	6,000	6,000	6,000	7,500
Repairs and maintenance	4,100	6,500	11,900	6,000	9,200
Royalty at 6 per cent. of income, equal \$0.28 per ton					11,200
Estimated gross annual cost of operation	\$67,800	\$68,000	\$78,200	\$140,500	\$180,500
Return from sale of products—					
Tankage				41,000	63,000
Grease					120,000
Miscellaneous residuals at \$0.10 per ton				4,000	4,000
Estimated total return				45,000	167,000
Estimated net annual cost of operation	\$67,800	\$68,000	\$78,200	\$95,500	\$6,500
Cost of operation per ton (40,000 tons)	\$1.69	\$1.70	\$1.96	\$2.39	\$0.16
Annual Fixed Charges: 200-Ton Plant					
Interest at 4 1/2 per cent.	\$15,600	\$19,800	\$31,400	\$26,700	\$31,300

Annual fixed charges	16,950	19,150	36,300	30,450	68,050
Estimated total net annual operating cost and fixed charges	68,600	67,450	93,500	100,150	109,750
Total net operating cost and fixed charges per ton refuse (20,000 tons per year)	3.43	3.37	4.68	5.01	5.495
Total net operating cost and fixed charges per ton garbage (40,000 tons per year)	1.72	1.69	2.34	2.51	2.755

¹ The items estimated to supplement the prices contained in the proposals include, where required, ramps, buildings or enlargements of buildings, garbage storage bins, employees' rooms and lockers, coal storage bins, office and weighing house, ash storage bins, ventilating equipment, garbage and ash-handling equipment, railway siding, track and wagon scales, grading, pavements and planting, water supply, sewerage, drainage and sewage disposal facilities. No allowance has been made for unusual or difficult foundation work.

² Includes 1 lb. chlorine per ton of garbage at 7 1/2 c. per lb. chlorine.

³ Profit.

⁴ Depreciation allowances varied to suit character of plant but all figured on sinking fund basis with 4 per cent. annuities added and 4 per cent. compound interest credited at end of each year.

⁵ The 100-ton plants would treat piggy residue (manure, garbage, etc., and manure). No piggy costs or revenues are included here, because Mr. Eddy does not recommend incineration for the piggy residue, but considers his combined piggy and piggy-waste disposal plant estimated by the Wannewetsch and Cobwell bids for drying and reduction, respectively, as shown in Table II. See also footnotes to Table II for basis of estimating tankage and grease values.

TABLE II—ESTIMATE COST OF GARBAGE DISPOSAL BY PIGGERY WITH DRYING OR WITH REDUCTION FOR RESIDUE

	Piggy With Wannewetsch Cobwell	
	Drying Plant	Reduction Plant
Construction Cost		
Cost of building piggy (6,000 head)	\$301,000	\$301,000
Cost of building refuse disposal plant	376,700	724,200
Total construction cost	\$677,700	\$1,025,200
Operation Cost		
Annual excess of return over cost of operating piggy	\$79,600	\$79,600
Net annual cost of operating disposal plant	69,700	41,700
Balance—Difference between annual excess return over operating cost for piggy and operating cost of disposal plant (profit)	9,900	37,900
Annual Charges		
Annual balance of receipts and expenditures for piggy and disposal plant (profit)	9,900	37,900
Fixed charges on piggy	20,700	20,700
Fixed charges on disposal plant	\$30,450	\$68,050
Total fixed charges	51,150	88,750
Net annual charges	41,250	50,850
Net annual charges per ton of green garbage, 1331 tons per collection day, 40,000 tons per year	1.03	1.275

¹ The main items are: Hog houses, \$212,000; miscellaneous buildings, heating and lighting, \$27,000; engineering omissions and contingencies (15 per cent. of \$262,000) \$39,300.

² The annual charges total \$91,800. Of this \$71,000 is for operating expenses, thus divided: Supervision and labor, \$33,700; freight, \$19,000; light, power and water, \$800; repairs and maintenance, (1 per cent. on \$301,000) \$3,010; carting, \$1,600; supplies and miscellaneous, \$13,000. The \$20,700 fixed charges on the \$301,000 of the capital cost include \$13,500 for interest and \$7,200 for depreciation, interest being figured at 4 1/2 per cent and sinking fund at 2 1/2 per cent (25-year life), with 4 per cent on accumulated amounts. The net profit is based on a purchase of 19,500 hogs weighing 125 lb. each, a death rate loss of 5 per cent and a total sale of 18,500 hogs weighing 200 lb. each, the total weight bought being 2,337,000 lb., at 8c. a pound, costing \$219,300 and the total weight sold being 3,700,000 lb. at 10c. yielding \$370,000. This gives \$150,700 for net gain in weight. Deducting from this \$91,800 gives \$58,900 as the net profit on the piggy or \$1.47 per ton of garbage delivered. The average cost of hogs bought for the existing Buffalo piggy during the 13 months ending Oct. 31, 1922, was 10.8c. per pound (but not including freight) and the selling price averaged 11.9c. making a gross gain of 1.1c. per pound, with no allowance for freight or death losses. Hogs from the Buffalo piggy, Mr. Eddy states, cost 10c. above the general market price because of the certainty that all of the piggy hogs have received double inoculation.

³ The higher net annual cost per ton for the Cobwell than for the Wannewetsch plant when each handles 100 tons of piggy refuse is due to the fact that in the 100-ton Cobwell plant the pre-drying in direct-heat driers is omitted, whereas in the 200-ton plant these driers are provided; this omission, Mr. Eddy states, makes necessary the installation of extra Cobwell reducers, which increase the cost figures as indicated. It is assumed that the unit yield and prices of grease and tankage will be the same from the green garbage and from the combined garbage and manure from the piggy. Two samples of piggy refuse, collected March 15, 1922, and Feb. 1, 1923 (the latter by a representative of Metcalf & Eddy), showed the following percentages after having been dried in a Wannewetsch reducer in use at a local packing house for rendering animal carcasses: Grease, 12.2 and 16.54; ammonia, 2.14 and 3.61; bone phosphate of lime, 2.28 and 3.39; potash (K₂O) 1.15 and 1; moisture, 7.97 and 7.69.

TABLE III—COMPARISON OF MOST ADVANTAGEOUS PROJECTS FOR (1) DIRECT DISPOSAL AND FOR (2) PIGGERY WITH AUXILIARY DISPOSAL

	C. O. Bartlett & Snow Plant (Cobwell Reduction Process)		Piggy Combined With C. H. A. Wannewetsch Drying Plant	
	Construction cost	\$694,800	\$677,700	
Net annual operating cost per ton (profit)	0.16		0.25	
Total net annual charges per ton	1.42		1.03	

To add fuel to garbage economically would require constant regulation according to the proportion of moisture contained in the garbage.

The control of fuel in this manner would require very close attention to operation and it is probable that lapses in control would occur and that offensive odors would escape during such times.

The only way in which fuel could be provided within the limits of the specifications of the bidders would be to add rubbish or coal with the garbage as fed into the incinerators. Control would depend upon the judgment of the men mixing the garbage and fuel. It is probable that offensive odors would be produced at times, and that fuel would be wasted at other times.

The estimates of cost indicate that disposal by any of the incinerators bid upon will be more expensive than that by another method.

None of the incinerators bid upon has been operated in this country on anything but a very small scale, if at all, and such operation as has been cited by the bidders appears to have been upon refuse and not upon garbage alone.

In view of these conditions we are of the opinion that none of the bids for incinerators constitutes the most advantageous bid, considering not only the cost of installation and operation but also the sanitary disposal of the garbage and freedom from odor in operation.

Because of the nature of the material the disposal of piggery refuse by incineration will be more difficult and more likely to create offensive odors than the disposal of green garbage by this method. For this reason plants combining a piggery and an incineration plant have not been included herein.

We are of the opinion that the installation of any of the incinerators bid upon is not justified for the disposal of so large a quantity of garbage as that produced at Buffalo.

Comparison of Combined Piggery and Residue Disposal Plants—Table II summarizes Mr. Eddy's comparative estimates of net annual charges on a combined plant in which 200 tons of garbage would be: (1) fed to pigs and the uneaten material and pig manure reduced in 100-ton plants of the Wannenwetsch drying type to produce fertilizer base, and (2) the entire 200 tons of green garbage would be treated in a reduction plant of the Bartlett & Snow or Cobwell type, yielding both fertilizer base and grease. The first cost of the combined piggery and drying plant would be \$677,700 and of the piggery and reduction plant, \$1,025,200, but taking all charges into account the net tonnage cost would be \$1.03 against \$1.27. The Cobwell combination is at a disadvantage here since it is based on the 50-ton Cobwell bid in which extra reducers were required because the preliminary driers included in the 200-ton Cobwell bid were omitted.

Final Comparison—Mr. Eddy compares (Table III) the most advantageous of the projects for treating the entire 200 tons of garbage with the most advantageous combined piggery-and-residue treatment plan; or a 2.3-ton Cobwell reduction plant using pre-driers and producing grease and fertilizer base and a 200-ton piggery and a 100-ton drying plant to produce (a) fat hogs and (b) fertilizer base, from the uneaten garbage and hog manure. This comparison shows first costs close together, \$694,800 for (1) against \$677,700 for (2), but net charges of \$1.42 and \$1.03 respectively.

Mr. Eddy expresses the belief that a piggery can be successfully built and operated in a sanitary way and that either the Cobwell or Wannenwetsch process can be operated without odor. He considers the value of the dried garbage from the Wannenwetsch process as "problematic" because its large fat content would probably lessen its value as a fertilizer base, but allowance was

made for this in the estimates. He points out that more operating skill is required for the Cobwell-Merz reduction process (as he calls the plant on which 200-ton bid was based) than for the Wannenwetsch drying process.

He points out that there are hazards, whichever of the two plans are chosen—of explosion in a reduction plant using solvent and of foot-and-mouth disease in the piggery. In case of the latter contingency, however, the supplementary drying plant would take care of half the garbage while, if the reduction plant were destroyed the entire volume would be subject to emergency disposal. Also, should a combination piggery and drying plant be built and the piggery subsequently abandoned, the drying plant would be available up to its capacity. Mr. Eddy also suggests that it "may be feasible, should circumstances justify it, to equip" the piggery-refuse drying plant for grease recovery.

Such objectionable odors as have occurred at garbage piggeries Mr. Eddy attributes to the piggery refuse, "which often has not been promptly and thoroughly cleaned up, and generally has not been disposed of in such a manner as to prevent offensive odors." Adequate provision for the prompt and sanitary disposal of piggery refuse "would be an important forward step" in garbage disposal by feeding to hogs. Either the Cobwell-Merz process for all the garbage or a combination piggery and Wannenwetsch residue drying plant "can be so constructed and operated," the report states, "as not to produce objectionable conditions in the neighborhood," but this "is dependent in both cases on skilled management."

Size and Cost of Plants Required in 1935—By 1935 it may be expected that the population of Buffalo will have increased to 640,000 (from about 500,000 in 1920). This would require a 240-ton plant, the approximate cost of which would be \$775,000 for a Cobwell-Merz green garbage plant and \$779,000 for a piggery combined with a Wannenwetsch auxiliary drying plant.

What Buffalo Should Do—Having shown that either of the alternative schemes selected from those bid on as most advantageous would require almost the same capital outlay, but would differ, as outlined, in gross and net operating costs and in total net annual charges, and in respect of risks, Mr. Eddy leaves the final choice to the city of Buffalo, but he adds this unequivocal advice: (1) The city should decide on one or the other scheme, then have complete designs made and request bids for its construction, and (2) the city should not overlook the fact, as has so often been done, that efficient operation is as essential as correct design and construction, for [italics ours—EDITOR], "*The primary object of the operation of such a plant should be the disposal of the garbage in a sanitary manner. The accomplishment of this object at the smallest expense, although of great importance, is an aim of secondary moment.*"

[Information from Mr. Schwartz, sent Sept. 13, indicates that a site has not yet been obtained owing to strenuous objections to every site proposed; also that the city is under a court order to close the piggery on Sept. 15 but has secured a hearing for Sept. 26 on a petition for a modification of the order to give the city time to find some other means of disposal, and had also filed an appeal from the order.—EDITOR.]

Engineering Literature

A MONTHLY REVIEW OF BOOKS AND A LISTING OF NEW PUBLICATIONS

A Guide to City Planning and Zoning

MANUAL OF INFORMATION ON CITY PLANNING AND ZONING: Including References on Regional, Rural and National Planning—By Theodora Kimball, Librarian, School of Landscape Architecture, Harvard University; Honorary Librarian, American City Planning Institute; Associate, British Town Planning Institute, Cambridge; Harvard University Press, London: Humphrey Milford; Oxford University Press, \$3.50.

Rarely does a new art or science have so devoted and competent a guide to sources of information as Miss Kimball has been for some years past. Her present volume surpasses her earlier reference works in variety and extent. The result is worthily called a Manual of Information.

Miss Kimball has obtained contributions from Flavell Shurtleff, secretary of the National Conference on City Planning, and from John M. Gries, chief of the Division of Building and Housing, U. S. Department of Commerce, on the work being done by those two agencies. There is also a note from Stephen Child on L'Union Internationale des Villes and the American Center of Civic Documentation, two ambitious projects as yet in their infancy. Other information given relates to various government and private agencies devoted to city planning; periodicals treating the subject; colleges and universities having courses in city planning; educational films; typical city planning reports, by years; and a table of municipal appropriations for city planning work, covering the past few years. The larger part of the book is filled with a Bibliography. This contains many hundred references to books and periodicals, classified and sub-classified in detail. The arrangement is numerical but there is a classified contents and an alphabetically arranged subject index.

Enough has been said to make clear that the Manual is a valuable guide that no practitioner or student of city planning or zoning should be without.

For Every Engineer

ESTIMATING BUILDING COSTS—By Charles F. Dingman, M. Am. Soc. C. E., M. Am. Soc. M. E., M. N. J. Soc. A. New York and London: McGraw-Hill Book Co. Flexible cloth; 4x7 in.; pp. 240. \$2.50.

In its small compass of 240 pages this manual contains more direct instruction on how to estimate costs than any other book known to the reviewer. There are more comprehensive volumes of data which are useful for estimating. The author gives a list of these books and urges all estimators to become familiar with them. While not lacking in essential data, his own volume is primarily a handbook of estimating processes. He undertakes to guide the reader through all the moves of estimating the cost of each operation of building work. Beginning with excavation, instruction is given, in separate chapters, on how to estimate brickwork, stone work, fireproofing, concrete, timber-framing, covering, finishing, roofing, plastering, and painting. There are general chapters on short-cut methods and on such estimating aids as remainder lists and equipment-rental tables. Plumbing, heating, electrical wiring and mechanical equipment are not considered, the author

advising that sub-bids be secured from specialists in these operations. For the beginner in problems of estimating, no better book of instructions is known. Even the experienced estimator will find it an aid in securing orderly thinking and practices. One could wish that every engineer would read it to the purpose at least of absorbing the fact that true estimating is one of the most complex problems of construction engineering.

Acoustics and Soundproofing

REVIEWED BY E. A. ECKHARDT

Physicist, Bureau of Standards, Washington, D. C.

ACOUSTICS OF BUILDINGS: Including Acoustics of Auditoriums and Soundproofing of Rooms—By F. R. Watson, Professor of Experimental Physics, University of Illinois. New York: John Wiley & Sons, London: Chapman & Hall, Ltd. Cloth; 6 x 9 in., pp. 155; 72 line cuts and halftones. \$3.

Most engineers and architects engaged in designing buildings have experienced the embarrassments presented by the acoustic problems encountered. These problems in their major aspects involve either the insulation of one part of a building from another so that the use of each may be enjoyed without interference from the other or the arrangement of a room or auditorium so that satisfactory hearing conditions may prevail within it. Within a period of two years two books covering this ground have appeared in the English language, both in America. Professor Wallace C. Sabine's "Collected Papers on Acoustics" was the first to appear. It includes reprints of the various papers published by the author during the progress of his pioneer work in the subject. The value of this collection is beyond question. From the point of view of the user, however, it is unfortunate that the material was not reworked into a systematic unit. Prof. F. R. Watson's new book "Acoustics of Buildings" gives a systematic presentation of the subject designed to facilitate the direct application of the information conveyed. It should therefore have great practical usefulness.

Prof. Watson has made very substantial contributions to the subject matter of his book and it is therefore quite natural that a large part of the reading matter is a recapitulation of his earlier publications. This has been done, however, without impairing the systematic character of the presentation. The book is divided into three parts dealing with the fundamental physical ideas involved, their application to the acoustics of auditoriums and the soundproofing of buildings respectively. The large number of practical examples taken from the author's wide experience gives concreteness to the abstract principles presented and makes it easier for the reader to make similar applications to problems of his own.

On one important question involved in the acoustics of rooms Prof. Watson is undoubtedly in error. He concludes that the acceptable time of reverberation for auditoriums for different volumes varies with the cube root of the volume. In auditoriums the problem is almost invariably to get the reverberation time small

enough, and in very large auditoriums the cost usually determines how closely the ideal may be approached. Prof. Sabine found a definite reverberation time to be the ideal, independent of the size of the room, but somewhat different for speech and for music. Departures from these ideal values are compromises made to meet some other requirements, usually to stay within the limits set by the purse. As a matter of compromise, large auditoriums will have larger reverberation times, but if no expense is spared in further reducing the reverberation time, improvement will certainly result.

Prof. Watson's book is well illustrated by photographs, diagrams and graphs, and as the first comprehensive systematic presentation in the English language will be welcomed by those seeking information on the questions of "Building Acoustics."

Timely and of World-Wide Moment

GERMANY'S CAPACITY TO PAY: A Study of the Reparation Problem.—By Harold G. Moulton and Constantine E. McGuire, with the Aid of the Council and Staff of the Institute of Economics. New York and London: McGraw-Hill Book Co. Cloth; 5x8 in.; pp. 284; 7 line cuts. \$2.50.

Timeliness and an able marshalling of facts and figures are shown in this readable discussion of the greatest question now confronting the world, Germany's capacity to pay war reparations. The last touches were given to the book in June so that, except for the recent spectacular further decline of the mark, the implications of the fall of the Cuno cabinet and the latest stages of the Franco-British notes, the book is up to the minute.

The authors make no attempt to name a sum which Germany can pay. The entire discussion is on her capacity to pay as indicated by reviews of what is involved in paying foreign debts, the German international trade balance for decades past (nearly always adverse), what Germany has already paid, foreign trade requirements, the German budget and monetary problems, a significant chapter on How France Met the Indemnity of 1871 (by loans, on which large interest payments are still being made) and the international phases of the reparations problems. There are seven appendices of supporting data, well designed to keep the main text free from burdensome statistics.

The two concluding sentences of the book sum up its spirit and the substance of such conclusions as are reached:

If one believes that the economic prosperity of the world will be promoted by the economic recovery and the restoration of the consuming power of Germany, he should favor her importation of large quantities of necessary food and raw materials and the exportation of correspondingly large quantities of manufactured goods. If, on the other hand, one believes that the disintegration of the German industrial system and the starvation of some millions of German people will promote the general welfare of the world, then he should welcome the continued curtailment of both German import and export trade.

Since the economic, social and political welfare of the world hinges so largely on the solution of this great German problem and any right and fairly prompt solution depends so much upon a sound public opinion, the book deserves wide reading. Certainly no one is qualified to pass judgment on Germany, France, England and the other countries involved without having in mind the major facts and principles which this book sets forth.

British House Sanitation

DOMESTIC SANITATION AND HOUSE DRAINAGE.—By Henry C. Adams, M. Inst. C. E., F. R. San. I., M. Inst. Water Eng., Consulting Engineer, Lecturer on Sanitary Science, Northern Polytechnic. [Oxford Technical Publications.] London: Henry Frowde and Hodder & Stoughton. New York: Oxford University Press, American Branch. Cloth; 6x9 in.; pp. 227; 193 line cuts and halftones. \$3.50.

British practice in house-design and construction as regards site, subsoil drainage, safeguards against dampness, the entire range of plumbing, earth privies and pail closets, refuse disposal, lighting, warming and ventilation are reviewed in this volume. School sanitation has a chapter but it is devoted wholly to water closets and urinals. There are short chapters on stables and cowsheds and a few pages on sanitary surveys.

The book is almost free from even late-Victorian notions on such matters as "sewer gas" and disease but contains these sentences, which might have been written when Victoria ascended the throne:

The close relation between malaria and the soil is shown in various ways. If the sun's rays are prevented from reaching the soil by the interposition of paving, malaria ceases. If a marsh be flooded from the sea and a layer of salt water covers the soil, malaria disappears. It is promoted by the rapid drying up of marshes and river beds, and is especially rife when such soil is broken up and fresh surfaces are exposed to the sun. Subsoil water or dampness is an essential condition of malaria, and is especially harmful if the subsoil water is stagnant. For this reason villages are built on hills, but the wind may carry the malarial poison long distances.

The only reference to mosquitoes found in the book is a single sentence which the author, after declaring that the "neighborhood of marshes is bad for dwellings" because of various gases given off by marshes, adds: "They (marshes) also cause an excess of aqueous vapor and form breeding-grounds for mosquitoes." Why mosquitoes are objectionable the author does not state.

Either the author can never have heard that malaria is spread not by "bad air" from whatever source, but by mosquitoes that breed in marsh and other stagnant waters, or else he is willing to accept what all sanitary entomologists and—in this country at least—sanitary engineers also have accepted for some two decades. This blemish on the book is all the more a pity because the volume is based on lectures to "students" (of what sort is not stated) who presumably take as sanitary law and gospel all that a member of the Institution of Civil Engineers says.

PUBLICATIONS RECEIVED

THOSE WHO WISH to get some of the latest ideas on the civil service as applied to cities will do well to get the August *National Municipal Review*, which is devoted wholly to a report of the National Municipal League's Special Committee on Civil Service, and supporting and opposing written discussions. The title of the report is "Employment Management in Municipal Service." Among the members of the committee are Henry S. Dennison, president, Dennison Manufacturing Co., chairman, and William C. Beyer and Morris B. Lambie, of the Philadelphia and the Minnesota Bureaus of Municipal Research. Fourteen persons contribute discussions, including Col. H. M. Waite, formerly city engineer of Cincinnati and (later) city manager of Dayton, Ohio; C. R. Woodruff, president and C. S. Shaugnessy, chief examiner, Philadelphia Civil Service Commission; and W. D. Foulke, president, National Civil Service Reform League. (National Municipal League, 261 Broadway, New York City; 50c.)

THE LIST OF ENGINEERING ARTICLES on irrigation and related subjects published from time to time by the U. S. Reclamation Service fills 31 pp. of the latest report of the Service, and, together with a list of books of 2 pp., has been printed in pamphlet form (Washington, D. C.). The articles are grouped into general and those relating to some one of the many projects and are further classified by authors. There are about 360 references to *Engineering News-Record*, *Engineering News*, and *Engineering Record*, of which 110 are general and 250 deal with a single project. Of the 28 projects, only one shows no reference to this journal or its two forerunners and for that project there are only two references. Under the Boise Project (Idaho, Arrowrock dam, etc.) there are 34 references to one of the three journals named above; under the Rio Grande Project (New Mexico-Texas, Elephant Butte dam, etc.) there are 25 references.

THE DIESEL OIL ENGINE FOR WATER-WORKS SERVICE, a paper by Dr. Charles E. Lücke, together with related papers and discussions, have been reprinted from the *Journal* of the N.E.W.W. Assoc. for June and may be obtained from the Worthington Pump & Machinery Corp., 115 Broadway, New York City.

NORTHWEST LUMBER AND ALLIED INDUSTRIES are listed in *Abbey's Register* which covers Arizona, Idaho, Montana, Nevada, Oregon, Washington, Alaska, and British Columbia. Logging operations, saw, planing and shingle mills, box, sash and door and other manufactures are included, besides wholesalers and brokers. (Portland, Ore.: The Industrial Service Co. Cloth; 6 x 8 in.; pp. 312.)

Foreign Papers and Reports

EIGHT ANNAS is the price of "Notes on the Identification of Timbers in Southern India," by R. B. Robinson, engineer, South India Railway, Simla, India. Among the plates are a number of enlarged colored transverse sections of various timbers.

A NOTABLE DISCUSSION of "Rainfall and Runoff" by R. W. Holmes, of Auckland, New Zealand, has reached this country in the form of a reprint of a paper read by Mr. Holmes before the New Zealand Society of Civil Engineers. Long-time precipitation records at Auckland, N. Z., Norfolk, Va., Hemel Hempstead, England, Padua, Italy, and Rockhampton, Australia, are presented graphically by years in terms of percentages of the average for the period for each of the stations named. Other diagrams show deviations from the averages for groups of consecutive years in percentages of the average. Mass rainfall curves are also presented. Some interesting diagrams illustrate a brief study of tree-growth rings in relation to rainfall. The text discusses all these matters and some runoff data as well.

LIKE MANY OTHER CITIES, Glasgow, Scotland, is studying the activated-sludge process. Tests were made in 1915-19 using two 50-U. S. gal. barrels equipped with Jones-Atwood air diffusers and quite recently a working-scale mechanical-agitation unit of about 240,000 U. S. gal. daily capacity was put in use. A pamphlet report dealing briefly with these tests and reviewing experiences in a few English cities, with incidental reference to American results, has been made by F. W. Harris, city analyst and corporation chemist of Glasgow, and has been published by the Conveners and Members of the Committee on Sewage Disposal of the Corporation of Glasgow.

SPACE RESTRICTIONS due to the war having come to an end, Sir Alexander Houston's annual reports on the Chemical and Bacteriological Examinations of the London Waters are resuming their old-time fullness. The report for the year ended March 31, 1923, extends to about 100 pp., including many tables and a few plates. The interesting and satisfactory results with chlorination as a substitute for storage to effect bacterial reduction were continued during the year and resulted in saving some \$80,000. Begun originally to save the coal used for pumping to the reservoirs for improvement of the water by storage, chlorination seems now to have established itself at London. By whatever means attained, Sir Alexander is a firm believer in making the water supply as hygienically safe as

possible before it is applied to the slow sand filters. Small-scale studies of mechanical filtration but without coagulation were continued in 1922-23 and are summarized in the report. Indications are that mechanical filtration will finally be introduced for London water, but apparently for prefiltration and at least in the beginning to cope with organisms that, from time to time, block some of the slow sand filters. The report details some interesting but thus far unsuccessful studies designed to throw light on the relation of fish and sea-gull dejecta to B. Coli in the large uncovered London reservoirs. The use of bacteriophages to distinguish B. Coli from human and various animal sources is another one of Sir Alexander's many adventures in the field of water bacteriology. This study has not yet brought success. (London: P. S. King & Son, Ltd.; 15 shillings.)

New Books and Revised Editions

BRIEF DRAWING.—By Ralph Curtis Ringwalt, J.L.B., Member of the New York Bar. New York and London: Longmans Green & Co. Cloth; 5x8 in.; pp. 214. \$1.50.

DER WASSERBAU.—III Teil des Handbuchs der Ingenieurwissenschaften. Erster Band: Die Gewässerkunde.—Von P. Gerhardt, R. Jasmund und H. Engels. Fünfte vermehrte Auflage. Leipzig: Wilhelm Engelman. Cloth; 7x10 in.; pp. 896; 64 illustrations in the text, mostly line cuts.

ENGINEERING NON-FERROUS METALS AND ALLOYS.—By Leslie Aitchison, Consulting Metallurgist to the Air Ministry, The Association of Drop Forgers and Stampers, etc., and William R. Barclay. With an Introduction by Engr. Vice-Admiral Sir George G. Goodall, K.C.B. (Late Engineer in Chief Admiralty). Part Pres., Inst. of Metals, and for Technical Publications. London: Henry Frowde and Hodder & Stoughton, New York: Oxford University Press, American Branch. Cloth; 6x9 in.; pp. 300; 82 line cuts and halftones. \$7.

Part I of this British book takes up general properties, construction, casting, working, heat treatment, mechanical properties and testing. Part II deals with copper, aluminum and nickel, each with its alloys; miscellaneous non-ferrous alloys; and the choice and specification of non-ferrous alloys.

HANDEBUCH DES MATERIALPRÜFUNGSWESENS für Maschinen- und Bauingenieure.—Von Dipl.-Ing. Otto Wawrzyniak, ord. Professor an der Technischen Hochschule, Dresden. Zweite vermehrte und vollständig umgearbeitete Auflage. Berlin: Julius Springer. Cloth; 6x9 in.; pp. 700; 611 line cuts and halftones. \$5 in Germany.

THE JOHNS HOPKINS UNIVERSITY LECTURES on Engineering Practice for 1922-23 include: The Relation of Highway Research to Modern Road Construction, by A. T. Goldbeck, chief, Division of Tests and Research, U. S. Bureau of Public Roads, Washington, D. C.; Possibilities for Steam Railroad Electrification, by Norman Wilson Storer, general engineer, Westinghouse Electric and Manufacturing Co., Pittsburgh, Pa.; and Power Development—Past and Future—by George A. Orrok, consulting engineer, New York City. Baltimore: Johns Hopkins Press; paper; 6x9 in.; pp. 90; halftones and line cuts. \$1.

MANUAL, AMERICAN RAILWAY ENGINEERING ASSOCIATION. Definitions, Specifications and Principles of Practice for Railway Engineering.—Edition of 1921. 6x9 in.; pp. 1004. Cloth, \$8; half morocco, \$10.

The revised Manual brings the information contained in the edition of 1915 up to date. By a very complete set of specifications, definitions and descriptions, and by references to the proceedings of the association, it provides a handbook on the following subjects in the field of railway engineering: Roadway, ballast, ties, rail, track, buildings, wooden bridges and trestles, masonry, signs, fences, crossings, signals, interlocking records and accounts, organization, water service, yards and terminals, iron and steel, rolling stock, railway and electric power, electricity, conservation of natural resources and uniform general contract forms.

LES METHODES MODERNES D'ORGANISATION INDUSTRIELLE.—Par L. Benoit, Ingenieur Des Arts et Manufactures. Avec Exemples du Calcul des Temps D'Usinage en Construction Mécanique par Hermann. Paris: Gauthier-Villars & Co. Paper; 6x9 in.; pp. 208; line cuts.

THE OFFICE OF THE CHIEF OF ENGINEERS OF THE ARMY: Its Non-Military History, Activities and Organization.—By W. Stull Holt. Service Monographs of the United States Government No. 27. Institute for Government Research, Baltimore, Md.: The Johns Hopkins Press. Cloth; 6x9 in.; pp. 166. \$1.

PHYSICS IN INDUSTRY.—Lectures Delivered Before the Institute of Physics by Archibald Barr, M. Inst. C. E., Emeritus Professor of Civil Engineering and Mechanics, Glasgow University; Sir James Alfred Ewing, M. Inst. C. E., and Clifford C. Paterson, M. Inst. C. E., with a Foreword by Sir J. J. Thomson, President Inst. P. Volume I. Oxford: Oxford University Press, London: Henry Frowde and Hodder & Stoughton, New York: Oxford University Press, American Branch. Boards, cloth back; 6x10 in.; pp. 79. 5s.

Prof. Barr deals with "Physics and Engineering Science with Special Reference to Mechanical Engineering" and Sir James Ewing and Mr. Paterson with "The Physicist in Engineering Practice" and "The Physicist in Electrical Engineering" respectively. Concise addresses in an appeal for research work, and particularly for research laboratories as an integral part of industrial works.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

The Cranberry Marsh Auger Pump

Sir—The new type of pump for low lift work as described by Eugene F. Deléry in *Engineering News-Record*, Aug. 9, 1923, p. 230, brings to mind extensive tests made by the writer in the spring of 1916, in collaboration with J. A. Schad and H. W. Tabor and under the direction of Prof. C. I. Corp of the University of Wisconsin.

The tests were made with an extremely simple type of screw lift pump designed by O. G. Malde, superintendent of the state Cranberry Marsh Experiment Station near Grand Rapids, Wis. These pumps were designed for lifts of 2 to 8 ft. The screw blade impeller operates in a cased opening built into the bottom of a large pit below the lower level of water (Fig. 3). The impeller is keyed to a shaft and the power is applied by means of a pulley attached to the upper end of the shaft above the upper level of water. As the pump operates, the level of the water in the pit increases until the water flows over a weir in the side of the pit.

FIG. 1—IMPELLER BLADES FOR AUGER PUMP

It is interesting to note that while the tests referred to were made for heads varying from 2 to 6 ft. and the New Orleans tests were made for heads of 3 to 14 ft., the efficiency of this crude 16-in. "Malde" pump is as great as that of the 4-in. rotary flow pump described by Mr. Deléry.

By referring to Fig. 2 it will be noted that the maximum efficiency seems quite constant, about 39 per cent, and that for this condition of maximum efficiency

the discharge ranges from 3 to 5 sec.-ft. It would be interesting to have these tests extended to a head of 14 or 15 ft. to verify the indication that the same maximum efficiency would be obtained, and to compare the results with those obtained from the pump patented by Mr. Deléry.

The tests made of the simple "Malde" pump show also a broad variation of speeds necessary for maximum efficiency at varying heads, a steadily increasing delivery for increasing speed at constant lift, a large increase of delivery at very low lifts and a well sustained delivery over the whole range of lifts, requiring, however, a necessarily increased horsepower input for the increased lifts. The "Malde" pump does not show a constant power curve for the range of lifts but for the maximum efficiency of operation requires an increasing power input for increasing heads, maintaining, however, a more or less sustained volume of discharge. The maximum efficiency range for the higher speeds, 540 and 650 r.p.m., is greater than for the lower speeds and it is quite probable that were the "Malde" pump operated at the increased speeds of 1,800 to 3,000 r.p.m. the range of maximum efficiency would also obtain over a greater variation in head.

It is doubtful if the reverse nature of the curves for efficiency and discharge, shown on Mr. Deléry's Fig. 3, would persist over a wide range of tests; it would rather

FIG. 2—PERFORMANCE CURVES FOR AUGER PUMP

tend to become more regular in outline. It is especially difficult to understand the almost vertical position of the discharge curve between heads of 6 to 7 ft. and the correspondingly almost horizontal position of the same curve between heads of 8 to 14 ft., the power input and efficiency presumably being approximately constant.

Further tests were made of the "Malde" pump after cutting off the lap of the blades, it being stated that it was easier to cast the impeller in this manner than with the blades overlapping. These tests uniformly showed a material decrease in the efficiency of the pump. Final tests

FIG. 3—DETAILS OF THE PUMP CASING
Showing its location in the floor of the pumping well.

were made with a bell mouth inlet to decrease the entrance loss. The resulting increase in efficiency due to this refinement was about 3 per cent.

The increased efficiency which might be expected in a pump with the refinements of the one described by Mr. Deléry over one of the crude type mentioned above is probably overcome by the friction losses within the chambers of the pump itself. Friction losses in the operation of the Cranberry Marsh pump are probably a minimum due to the comparatively large section of the pump pit as compared with the impeller orifice, and the relatively slow velocity of the water with regard to the pump pit walls

Pittsburgh, Pa.,

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

Chemists Discuss Sewage and Water Supply

Activated Sludge and Filtration Main Topics at Section Meeting of American Chemical Society

Special Correspondence

Local interest as well as an unusual attractive program was responsible for two popular and enthusiastic sessions of the Division of Water, Sewage and Sanitation, at the 66th meeting of the American Chemical Society, Milwaukee, Wis., Sept. 10-14. John Arthur Wilson's paper on the "Scientific Development of the Activated Sludge Process at Milwaukee" was the center of a discussion that involved many of the sanitary chemists and engineers who have followed this project with intense interest. This formed a part of a symposium that added considerable to the general knowledge of this method of sewage disposal.

Activated Sludge Symposium—Dr. F. W. Mohlman, chief chemist of the Sanitary District of Chicago, discussed the filtration of activated sludge. Operation on a working scale of four types of filters (Simplex plate and frame, Worthington platen, Oliver and American continuous) at the Des Plaines and Calumet plants has shown that treatment of activated sludge with filter alum before filtration flocculates and coagulates the solids and greatly improves filtration. Alum has proved to be superior to sulphuric acid from a practical standpoint. The cost is about the same in each case and the very small addition of alum to the sludge is of negligible significance. Experience at the Corn Products plant at Argo, Ill., seemed to confirm the superiority of alum over other coagulants. Other conclusions brought out in this work are that dilution of sludge frequently accelerates filtration and that the moisture content and biological conditions of the sludge are controlling factors in filtration.

Prof. Edward Bartow, head of the chemistry department at the State University of Iowa, described the treatment of waste from a packing house at Mason City, Iowa. In 1921 an activated sludge plant had been constructed there. Originally it contained a sediment and grease tank, an aeration chamber and a Dorr clarifier. It did not accomplish complete treatment, although great improvement was noted. The excess sludge was mixed with tankage and sold as fertilizer. In remodeling the plant there have been added a Dorr clarifier and a grease skimmer for the removal of heavier solids and greases and a new aeration tank which will double the aeration capacity. Putrefaction in the clarifier is prevented by returning the clarified effluent to the aeration tank during periods of low flow.

Problems in Water Filtration—Dr. George N. Prentiss, chemical director of the C. M. & St. P. R.R., reported

Ulen and Co. Submits Only Bid on Moffat Tunnel

Ulen and Co., New York, was the only contractor who submitted a regular bid for construction of the Moffat Tunnel, Colo., for which the total amount of the Ulen bid was \$6,075,000. At the time of going to press the tunnel commission had announced no decision, but word from its New York office was to the effect that the Ulen company had failed to be awarded the contract. Whether the commission will readvertise, or do the work itself is not, then known.

that a committee of chemists from the local section of the society had investigated the advisability of filtering the Milwaukee city water supply. Their recommendation—by majority opinion—was that the filtration project might well await the solution of the sewage disposal problem since at present the city water apparently offers no menace to the health of the community. Most of the sanitary chemists present seemed to agree with a statement by one of their number that "chlorination without filtration gives us a pretty slender thread on which to hang the health of half a million people."

Dr. W. D. Hatfield of the filtration plant at Highland Park (Detroit) Michigan offered a modified hematoxylin (colorimetric) test to replace the tedious gravimetric method of determining soluble aluminum in filtered waters. Apparently when restricted to a limited range of hydrogen-ion concentration, the method is satisfactory for all practical purposes.

Five Killed in Collapse of Scotia Bridge Span

Falsework Under Skew Arch Gives Way As Concrete is Being Poured—State Engineer Reports

One of the spans on the Schenectady-Scotia reinforced-concrete bridge spanning the Mohawk River and the New York State Barge Canal and known as the Great Western Gateway collapsed the afternoon of Sept. 17, while the last concrete was being poured on the span. Five men are supposed to have been drowned or crushed under the timbers and concrete. These included four workmen, and the engineer for the construction company, Kenneth Davidson. The span which collapsed was the twenty-fourth span, and it went down without warning.

An investigation has been made of the accident by State Engineer Dwight B. LaDu, who reports as follows:

"This department's investigation of the causes leading to the collapse of a span of the Schenectady-Scotia Bridge, discloses the fact that the falsework on the twenty-fourth span of the structure collapsed at 5:15 p.m. Monday, Sept. 17, while concrete was being poured on the two downstream arch ribs of the span. The pouring of the concrete was practically complete at the time the span gave way. This span, which is the first from the Scotia end of the bridge, is on a sharp skew, the falsework being supported by over 96 piles, some additional piles having been placed at the suggestion of the assistant engineer in charge of construction. These piles support the timber bents which, in turn, support eight trusses, two under each rib. The piles supporting this falsework were driven to at

COLLAPSED SPAN OF SCHENECTADY-SCOTIA BRIDGE

least a 15-ton penetration which gave ample bearing power to support the load of the superimposed falsework and the concrete in the arches.

It is the opinion of this department that there was some slight lateral movement in the piling which resulted in an accentuated movement of the blocking and wedges under the trusses. This movement resulted in a general turning movement of the trusses due to a considerable extent to the sharp skew on which they had been erected. This brought about a general collapse of the falsework and concrete with the resulting loss of life.

"This department, while supervising the construction of this bridge, has no responsibility for the stability of the falsework during the erection of the arch ribs and, under the contract, has no authority to determine the type of falsework to be used. It should be said, however, that the department had already directed the contractor at various times to strengthen the falsework under the spans. No settlement of the abutment or pier has been detected and the state will suffer no monetary loss due to the collapse of the span."

PLANS DRAWN BEFORE WAR

Plans for the bridge were first drawn before the World War, but construction upon it was not started until three years ago. Twelve spans had been completed at the time of the accident. The structure has a total length of 4,436 ft. comprising 23 spans of lengths varying from 106 ft. to 120 ft., and one span across the Barge Canal channel of 212 ft. Plans called for width of roadway of 40 ft. between curbs with double tracks for electric cars in the center, and 6 ft. sidewalks. Four arch spans, each 106 ft. long, cross the river channel to the triangular pier on Van Slyck Island, where the bridge turns at an angle of 54 deg. The crossing of Van Slyck Island is in three arch spans 110 ft. each, one arch span 117 ft., all square-ended, and four arch spans 120 ft., each on a skew of 18 deg. Then comes the 212-ft. span across the barge canal which is on a skew, then six 120-ft. skew spans and an anchor pier on the far side of Hog Island, and five more skew spans of 120 ft. each. The structure between abutments is divided into five sections by two anchor piers and the massive piers of the channel span.

On the Scotia end of the bridge for

Money Asked for Philadelphia Port Improvement

Request has been made by the Department of Wharves, Docks, and Ferries of the City of Philadelphia to have an item of \$3,270,000 provided for its use in the loan bill to be submitted in November to popular vote. This sum is asked to carry on the work of the department during the year 1924, and is divided as follows:

Pier 84 South:		
Completion of construction work	\$350,000	
Completion of water supply, electrical work, plumbing, heating and sprinkler system	300,000	\$650,000
Pier 82 South:		
Completion of construction work	\$2,200,000	
Completion of water supply, electrical work, plumbing, heating and sprinkler system	300,000	2,500,000
For the construction of six (6) mud screws at \$20,000 each		120,000
Total		\$3,270,000

Pier 84 is at present almost complete, but funds are not available for the remaining work. On Pier 82, the substructure has been finished, and the item for construction work on this pier will provide for the entire superstructure.

The request has been made by report of the Director of the Department to the Mayor, and will be forwarded to City Council later. Public works of all kinds have been brought to a standstill

Temporary Relief Sought for Springfield Traffic

Following destruction of the North End bridge at Springfield, Mass., by fire Sept. 8, (*Engineering News-Record*, Sept. 13, p. 451) temporary measures for traffic relief between Springfield and West Springfield are being sought by city and county officials. Several plans have been considered but no definite project yet has been decided upon. Proposals to span the Connecticut River with an army pontoon bridge were discarded as being too expensive. No report has been made yet as to whether piers can be used without considerable reconstruction, so the feasibility of a temporary timber structure upon the old site remains uncertain.

The county commissioners of Hampden County have been trying to discover if they possess authority, through the enabling act of 1872 which authorized construction of the destroyed structure, to build a new bridge. It seems to be prevailing legal opinion that new legislation will be necessary.

Apportionment of cost of removing wreckage, as well as providing temporary traffic relief, has been a subject the county commissioners and city councils of the two towns affected have been perplexed by, though the question of wreckage removal cost has been waived, exigencies demanding that the five twisted steel spans be taken from the river before any possibility of ice and consequent jamming arises.

Partial telephone and electric light service was resumed the day following the fire by the placement of temporary cables in the river bed.

TWO VIEWS OF NORTH END BRIDGE, SPRINGFIELD, DESTROYED BY FIRE, SEPT. 8

a distance of 940 ft. the approach consists of an earth embankment.

The new structure is to replace an old steel toll-bridge which crosses the river about 1,200 ft. to the east. It will be paid for jointly by the State of New York, the City of Schenectady, the County of Schenectady and the Village of Scotia. The contract plans were prepared by Frank M. Williams, then state engineer, from a design by B. H. Davis, consulting engineer.

in Philadelphia because the borrowing capacity of City Council has been completely exhausted. It is now intended that a large loan, which may reach a total of \$40,000,000 or \$50,000,000, will be submitted to the voters in November. This new loan will include funds for completion of the Delaware River Bridge, provision of subway and elevated railway lines, the improvement of the port facilities, construction of sewage disposal plants, etc.

Plan Elevator for Vancouver

To provide increased storage accommodation for the rapidly-growing shipments of wheat from the prairie provinces, an additional grain elevator with capacity for 2,000,000 bu. is to be erected at Vancouver, B. C. immediately. Work on the structure is expected to occupy four months, but it is expected to have a portion of it ready in time to handle the 1923 crop.

New Road Gives Entry to Chicago From Indiana

An agreement has been entered into by the Indiana State Highway Commission and Lake County to construct a paved highway from a point near Dyer, Ind., to 106th St., Chicago. The pavement from 106th St. for a distance of 1.56 miles will be approximately 69 ft. wide. The entire project is about 16 miles long. A large portion of it is already paved. The highway commission is to pay one-third the cost and Lake County two-thirds. Under terms of the co-operative agreement the highway commission will construct the road from the intersection of the Evansville-Chicago road with the Lincoln Highway to the north line of St. John township, Lake County. The county will build the road from this point to Roby, where State Roads Nos. 2, 8, 43 and 48 converge at the intersection of Calumet and Indianapolis avenues.

Public Ownership League Holds Convention

Protest was raised against Henry Ford's proposal to secure the Muscle Shoals property at the annual convention of the Public Ownership League of America held at Toronto Sept. 11-14. The convention passed resolutions protesting against any move on the part of the U. S. Government to accept the Ford proposal, on the ground that the power should remain the property of the people.

Outstanding among the various addresses was that delivered by Sir Adam Beck, chairman of the Ontario Hydro-Electric Commission, who gave a comprehensive account of the rise and progress of the provincial hydro-electrical system. He urged the immediate development of new services of power supply.

Earl D. Thompson, secretary of the League, discussed "Super-Power the Supreme Issue." Hon. George W. Joseph of Portland, Ore., dealt with "Public Ownership Possibilities in Oregon" and urged the saving of the water powers for the enrichment of the state. "Public Ownership of Telephones in Manitoba" was the subject of a paper by Mrs. J. E. Lowry.

The public ownership of railroads was advocated by Amos Pinchot, of New York, who considered it the most important problem before the public and asserted that the industrial concerns and railroads were spending probably millions yearly to convince the public that it cannot run its own railroads.

A resolution was adopted calling for a nationwide superpower system publicly owned and operated throughout the United States, steps to be taken at once to co-operate with members of Congress and others interested with a view to drafting a suitable measure. Charles K. Mohler, consulting engineer, Chicago, contributed a paper on "Essential Features of a Model Super-Power Law." George Wright, of the Toronto Transportation Commission, gave a history of the street railway system, claiming that it was a true type of successful public ownership. A. Emil Davies of London, England, chairman of the Nationalization Society, gave details of the progress of public ownership in Britain.

Traffic Is Chamber Topic

A general survey of the waterways of the country as the basis for preparing a comprehensive plan for their development by the government, the establishment of joint rail and waterway routes and dates, and the regulation of common carriers on waterways was discussed at the meeting of the committee on the development of waterways and the co-ordination of rail and waterway service of the United States Chamber of Commerce at its meeting on Sept. 11. The committee hopes that it will be able to outline methods of increasing the traffic on the Great Lakes and on the government barge line on the Mississippi as a means of relieving the general transportation situation.

Chicago Station Permit Issued

A building permit for the construction of the \$6,000,000 Union Station building in Chicago has been granted to the Terminal Building Co. This is Chicago's second largest building project and will be the largest one-level terminal in the world. It will be surpassed in size only by the Pennsylvania and Grand Central terminals in New York City, which are both two-level terminals.

Seattle Engineers' Home Moved

IN ORDER to make way for the Community Hotel, contract for the construction of which was recently let, the building occupied by the Seattle Engineers Club was blocked up 12 ft. on cribbing and moved more than a block from its old location. The building is only six years old and has a replacement value estimated at more than \$60,000. It was recently purchased by the Plymouth Church and was moved to their property. The Engineers Club will lease from the church trustees for a five-year period. As it cost but \$20,000 to move the club building, it is considered a good investment, particularly because in its new site a basement story will be built on to make room for rentable store space. During the time the building was being moved regular meetings of the Engineers Club, lunches and all normal activities were uninterrupted. Heating was accomplished by electric connections and by special heaters. Water supply and sanitation were also maintained throughout the five weeks the building was being moved.

Plans Complete for Session of Construction Council

First Annual Meeting of Body to Be Held at Engineering Societies Building Sept. 21

The first annual meeting of the American Construction Council will be held at the Engineering Societies' Building tomorrow, Sept. 21, at 2 p.m., which session is to be followed by a dinner meeting at the Hotel Commodore at six o'clock and by an evening session in that hotel. Tomorrow morning there will be a meeting of the board of governors and the executive committee at the home of the president of the Council, Franklin D. Roosevelt. On the morning of Sept. 22 there will be meetings of the committees of the Council by special appointment.

AFTERNOON MEETING

The afternoon session will be opened by Mr. Roosevelt, who will be followed by H. L. Wheeler, vice-president of the Union Trust Co. of Chicago. Important topics to be discussed after Mr. Wheeler's address include: "Local Autonomy and National Organization in the Construction Industry," by Harry T. Stevens, president, New Jersey Building Congress, and Richard A. Wolff, secretary, New York Building Congress; "Apprenticeship, Vocational Guidance and Craftsmanship in the Construction Industry," Fred F. Moran, New York Building Congress; "Reduction of Unemployment in the Construction Industry," A. P. Greensfelder, Fruin-Colnon Co., St. Louis; "The American Construction Council's Program on Research," which is a report of the committee of the American Construction Council on public information and research, given by Dwight L. Hoopinger, chairman. After the first three named addresses, committees of the Council having to do with these three subjects of discussion will report and discussion upon the report will be invited.

EVENING SESSIONS

The dinner session will be opened by an address by the executive vice-president of the Council, D. Knick Backer Boyd. The possibilities of an international exhibition of the construction industry during the sesqui-centennial exhibition in Philadelphia will be explained by the chairman of the executive committee of the Exhibition Association, Ernest T. Trigg. This will be followed by an address by E. T. Brunner, editor of *American Contractor*, on "A Look Into the Future of the American Construction Council."

At the evening session, which is scheduled to begin at eight o'clock at the Hotel Commodore, there will be a discussion by representatives of the twelve constituent groups of the Council on "What the American Construction Council Can Do to Help Our Branch of the Construction Industry." These will be followed by officers' reports, reports of the committees on resolutions, meetings of the twelve constituent groups for election of the board of governors, and the annual meeting of the board of governors.

Should the evening meeting not be finished by 10 o'clock it will be concluded Saturday morning.

Random Lines

BOY WANTED ABOUT 71 YEARS OF age for blueprint work.—*Buffalo News.*

Well! There's one field left open when we get too old for real engineering.

* * *

More "Engineers"

An advertisement in the *Bridgeport Post*—

WANTED—Two men, reliable, to qualify for positions as business engineer; salary \$3,000 and up; willingness during spare time to acquire understanding of this work more essential than previous experience.

There should be admitted to the profession, too, Mr. Ben Gardner, dwelling engineer of Sacramento, Cal., who advertises that he has keys for anything and that he repairs doors, windows, locks, porches, roofs, stairs, chimneys and furnaces; the electric sign engineers of the Thos. Cusack Co., whom a *Buffalo* paper lauds and an unnamed amusement engineer, who figures prominently in the advertising columns of the *Philadelphia Record*. *Good House-keeping*, not to be outdone, has now a department of Household Engineering.

And out in Seattle, Floyd Foster Barnes, human engineer, is lecturing on such typically engineering subjects as "Psycho-Analysis and Love" and "Thoughts Are Things."

As a special feature of the Golden Jubilee Celebration at Lakeside, Ohio, there is to be a trilogy of pageants and the management is pleased to announce that "Mrs. Ruth Mougey Worrell, pageant engineer of wide and highly successful experience, has been secured as author and director of this feature of our celebration."

* * *

Blow Warm, Thou Air Blowers

Dimitrie Joanowici, Rumanian inventor who claims to be able to keep the harbors of Montreal and Quebec and Cabot Straits open for the winter navigation, is asking the sum of \$2,000,000 as recompense for his secrets. He stated recently that he had placed his proposals before Hon. Ernest Lapointe, Minister of Marine and Fisheries, and that Mr. Lapointe had given him a good hearing. Mr. Joanowici stated Mr. Lapointe had informed him that the matter would be considered by the departmental engineers before any conclusion was reached. Mr. Joanowici's plan for keeping Cabot Straits open involves the use of a number of powerful electrically-driven air blowers which would be placed on the coasts of Newfoundland and Cape Breton. They would be used to divert the course of the ice so as to keep the straits open.

The above note was sent in as a serious communication by our Montreal correspondent. On reading it over we concluded it belongs in this column.

Hetch Hetchy Power Distribution Question in Limelight

M. M. O'Shaughnessy, city engineer of San Francisco, has recommended to the board of supervisors that the city immediately begin suit to condemn the local distribution system of private power companies for use in distributing Hetch Hetchy power. This would provide definite information on which the voters could choose the alternative of wholesaling power or acquiring a distribution system.

Attention concentrates on the subject at this time because the Moccasin Creek plant, the first Hetch Hetchy unit, is nearing completion with a capacity of forty-five per cent of the city's requirements.

Without reference to Mr. O'Shaughnessy's report, the board of supervisors passed by a vote of fifteen to two a resolution putting that body on record as "unequivocally opposed to the policy of entering into any contract, lease or agreement of any kind for the distribution of Hetch Hetchy power to or through any private corporation," and declaring that absolute municipal ownership and direct distribution to consumers of Hetch Hetchy power is the city's basic policy. The resolution also urged the appointment by the mayor of five citizens to negotiate with the private companies for the purchase of a distribution system and further instructed the city engineer to prepare plans and specifications for a distribution system capable of supplying all electric light and power requirements within the city. The power companies have already stated that their systems are not for sale.

Approval by popular vote is necessary before funds would be available for purchase or duplication of distributing systems. Mr. O'Shaughnessy's recommendation is for wholesaling power until final decision is made, thus avoiding the loss of \$2,000,000 annually that would result from failure to utilize Moccasin Creek power.

Applications for Power Sites in Utah Conflict

The so-called Split Mountain site near Vernal, Utah, on the Green River, has come into prominence through conflicting applications to develop power at that point. One application has been filed with the state engineer of Utah by a Mr. Ratliff, Vernal citizen, for a combined power and irrigation project, and the other application has been filed with the Federal Power Commission by the Utah Power & Light Co. for a preliminary permit for a power development. Mr. Ratliff has also requested the Department of the Interior to grant him an irrigation right for 16,000 acres of land at or near the site, and as he is reported to be backed by Col. A. E. Humphreys, of Denver, Col., it is expected that he will be in a position to start developments at an early date, whereas the Utah Power & Light Co. has no immediate prospect of a market in the region of the power site and would consequently have to develop a market before it could undertake the development. The Federal Power Commission will not be called upon to make a decision in this case until the Ratliff interests make formal application to it for a preliminary permit.

Wallace Finds Removal of Davis Is "Backward Step"

In forcing out A. P. Davis as director of the Reclamation Service, Secretary Work of the Department of the Interior took a backward step and for reasons contrary to the policy of many industrial enterprises, L. W. Wallace, executive secretary of the Federated American Engineering Societies, declares in a statement which points out successes attained by engineers in business.

"Requesting the resignation of Mr. Davis," says Mr. Wallace, "Secretary Work gave as his reason that he believed the Reclamation Service should be administered by a business man and not by an engineer."

"The only inference one can draw from this is that he considers an engineer not competent to direct the business phases of a large enterprise that is essentially engineering in character, as is the Reclamation Service. The clear implication is that Secretary Work, a professional man, being a doctor, is of the opinion that members of the professional group of engineering are not successful administrators of business and particularly those lines of business that are essentially engineering."

"Evidently the Secretary does not know that many technical directors of large works within and without the Government Service have ably directed such projects both from a business and a technical point of view. It would appear that the Secretary does not know that one of the marked tendencies in recent years has been the placing of technically-trained engineers, chemists and scientific men in charge of large industrial and commercial enterprises."

"Obviously he does not know that many engineers, who, after they had secured their technical education and experience and while firmly establishing themselves as engineers, have coincidentally come into prominence because of their business ability. One of the Secretary's colleagues on the Cabinet, the Secretary of Commerce, Herbert Hoover, is an illustration."

Advertising Signs to Be Removed From Connecticut Highways

On the ground that they are a menace to the safety of the traveling public, the Connecticut State Highway Department has ordered removal of all signs abutting the highways in an illegal way. Co-operating with the state police department and the motor vehicle department, steps have been taken to remove immediately many new advertising signs which have come to the attention of the state officials.

Orders have been issued to all district supervisors of the highway department to notify foremen in their jurisdictions to see that all such signs are taken down at once. At the same time, the department has notified its divisional officers that the attention of the state police will be called to all such violations.

Statutes prohibit the use of any sign, large or small, within the highway limits. In this class is included the great variety of posters which are frequently seen tacked to telephone poles and trees. The state police department estimates that no less than 5,000 signs of all descriptions were removed during the last year for various causes.

Council-Manager Plan Adopted by Portland, Maine

By a vote of 9,924 to 7,691 the electors of Portland, Me., approved a council-manager charter on Sept. 10. There were 6,931 votes for retaining the present charter and 640 for a revised charter prepared by a committee headed by C. S. Chaplin, mayor of Portland. Some 72 per cent of the registered voters took part in the election. The new charter will go into effect next January.

New Precedent in Rail Valuation Established by the I.C.C.

The Interstate Commerce Commission has finally disposed of the first two contested cases of tentative valuations and has fixed "final single sum values" of \$45,000,000 on the San Pedro, Los Angeles & Salt Lake Railroad Co. and \$23,245,257 on the Atlanta, Birmingham & Atlantic R.R. These figures are substantially the same as the tentative values announced some time ago and have been fixed at extended hearings in which the protests were completely overruled.

The findings in regard to the Atlanta, Birmingham, & Atlantic are regarded as having established a precedent for further valuation work in that, although the Atlanta line has consistently been losing money, the commission states that the valuation could not be based upon the "junk worth" of the property inasmuch as it is rendering a distinct service to the territory traversed.

As the Union Pacific, the controlling company for the San Pedro, Los Angeles & Salt Lake R.R., values it at \$75,000,000, it has announced that it will protest the findings of the Interstate Commerce Commission. The Union Pacific claims that this value of \$75,000,000 is the value of the railroad as a going concern, but the Interstate Commerce Commission maintains that it is not limited to such considerations and that the "final single-sum value" which it has ascertained for the property of this carrier is based upon a careful consideration of all the relevant facts that have come to its attention. It is, in the judgment of the commission a value which it is authorized by the Valuation Act to ascertain and report. "The fair value of the property which the carrier holds for and uses in the service of transportation and upon which it is entitled to earn a fair return."

Civil Service Examinations UNITED STATES

For the civil service examinations named below, apply to the United States Civil Service Commission, Washington, D. C., or to any local office of the commission.

Junior Engineer—Vacancies in the Bureau of Standards, Washington, D. C.; examinations to be in the subjects of ceramic, chemical, civil, electrical, mechanical and radio engineering, and the engineering of materials; positions at entrance salaries ranging from \$1,200 to \$1,590 a year plus increase of \$20 a month.

Examinations will be held throughout the country on December 5, 1923.

CANADA

For the following civil service examination, apply to the Civil Service Commission, Ottawa, or to the postmaster in any of the large cities of Canada.

Geologist—For the Geological Survey, Department of Mines, Ottawa, Canada, for work in the field, surveys and mapping, explorations, reports for publication, and other related work; initial salary \$3,600 per year.

Application must be made before September 29.

Engineering Societies

Calendar

Annual Meetings

NEW ENGLAND WATER WORKS ASSOCIATION, Boston, Mass.; Annual Convention, Burlington, Vt., Sept. 18-21, 1923.

INTERNATIONAL ASSOCIATION OF STREET SANITATION OFFICIALS, Chicago, Ill.; Annual Conference, Chicago, Sept. 27-28, 1923.

AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 8-11.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 17-20.

AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga., Nov. 12-16.

CITY MANAGERS ASSOCIATION, Lawrence, Kansas; Annual Meeting, Washington, D. C., Nov. 13-15.

The San Francisco Engineers Club at a luncheon August 29 was addressed by Charles G. Hyde, professor of sanitary engineering, University of California, on his observations and experiences while in Europe, from which he had recently returned.

The Western Society of Engineers Oct. 1 will hear William Frances Gibbs, president Gibbs Bros. Co., New York, speak on "Reconditioning the Levithan." On Oct. 15 transportation of perishable freight will be discussed by C. H. Nelson, manager refrigeration department, Aitchison, Topeka & Santa Fe Ry., from the standpoint of railroad requirements and by J. W. Ingham, chief engineer, Railways Ice Co., on the engineering of refrigeration. Several engineers and officials of the Peoples Gas Light & Coke Co., Chicago, who studied European practice of gas manufacture and distribution this summer will present on Oct. 29 a symposium on their findings.

Personal Notes

VIRGIL C. LEE, of Anderson, Ind., has been named engineer for the Fort Wayne district of the Indiana State Highway Department to succeed O. B. Kercher, of Goshen, who resigned several weeks ago. Mr. Lee is a graduate of Purdue University. He will be in charge of state highway system in 13 counties.

A. G. SCHAMBERGER, JR., formerly draftsman with Bethlehem Steel Co., Bethlehem, Pa., has been made estimator and draftsman with the Community Steel Corp., and is located at Buffalo, N. Y.

R. W. MCCORMICK, a professor in Rose Polytechnic Institute at Terre Haute, and the first chairman of the Indiana State Board for Registration of Professional Engineers and Land Surveyors, has resigned from the board.

FRED F. FRIEND, formerly hydraulic engineer for the Electric Bond & Share Co., New York City, has moved to California and is now chief engineer of the Palo Verde Drainage and Levee District.

J. W. BLAIR, Texas City, Tex., is now associated with John Monks & Sons, contractors, New York City, as general foreman on construction of sugar refineries. Mr. Blair was formerly general superintendent on construction of the Galveston Causeway.

R. T. MCKAY, until recently concrete engineer with Mamer Co., Benton Harbor, Mich., has been made concrete engineer on the staff of Brussel & Viterbo, consulting engineers, Chicago, Ill.

WILLIAM D. SMITH, formerly chief draftsman for the Port of Tacoma, Tacoma, Wash., is now designer for Hedrick & Kremers, consulting engineers, Portland, Ore.

H. P. HEVENOR, consulting engineer and in this capacity connected with Dwight P. Robinson & Co., Inc., for the past year, has opened offices at 110 E. 42nd St., New York City. For 18 years Mr. Hevenor has been a specialist in track design and construction, for a short time with the Brooklyn Rapid Transit Co. and for five years in the office of the chief engineer of the New York, New Haven & Hartford R.R. In 1916 he entered private practice under the firm name of Engel & Hevenor, and installed track on the New York Seventh Avenue subway, Third Avenue Ry., and Eighth and Ninth Ave. R.R., also did special track construction for the Trenton & Mercer County Traction Co., Capitol Traction Co., Washington, D. C., Newport News & Hampton Railway Gas & Electric Co., Delaware, Lackawanna R.R., New York, New Haven & Hartford R.R. and the Connecticut Co.

GEORGE JEROME, consulting engineer, has been appointed city engineer of Detroit, Mich., by John W. Reid, who became commissioner of public works Sept. 1. Mr. Jerome at the time of his appointment was engineer for the village of Ferndale and conducted a private practice in engineering in Detroit, where he was formerly assistant city engineer.

T. E. MOSS WHEAT, civil engineer, announces the opening of offices at 306 Murphy Bldg., Detroit, Mich., for the practice of civil and structural engineering, surveys, reports, designs, supervision and appraisals, and includes the announcement of the dissolution of the firm of WRIGHT, NICE & WHEAT, Detroit, Mich. Mr. Wheat is a 1914 civil engineer graduate of the University of Michigan, served in the Bureau of Public Works, Manila, and on the erection of a radio station at

Cauacuo, P. I., and in the United States as superintendent for the Division of Military Aeronautics of production of aircraft hangars at various factories and later in charge of reclamation of hangar buildings. After the war Mr. Wheat was connected with Smith, Hinchman & Grylls on St. Clair River surveys, city layout including sewer design, water-works and streets, and other construction work.

C. E. PUTNAM, Tacoma, has been appointed city engineer of Tacoma, Wash., to succeed J. C. Manley, resigned. Mr. Putnam has had 20 years of experience in engineering, and since 1921 has been construction engineer in the Tacoma city service.

R. F. RAGLAND, formerly assistant engineer, Yellowstone National Park, is now resident engineer for the Bureau of Public Roads, U. S. Department of Agriculture, in charge of highway construction at Seward, Alaska.

McKELVEY CONSTRUCTION CO., St. Louis, Mo., has opened a branch office in the Hammond Bldg., Detroit, Mich., with H. E. Anderson in charge. Mr. Anderson has been associated with the company since its organization two years ago.

E. W. BEATTY, Montreal, president of the Canadian Pacific Ry., accompanied by several of the directors of the railway started on Sept. 7 on a tour of inspection of the lines between Montreal and the Pacific Coast.

OTTO M. RAU, a power engineer for many years connected with the Edison General Electric Co. of New York, has been appointed consulting engineer of the Giant Power Survey Board of the State of Pennsylvania. Mr. Rau has established an office in the Fuller Building, 10 South 18th Street, Philadelphia. During the war, Mr. Rau was consulting engineer in the power section of the Emergency Fleet Corporation.

Obituary

SHEPLEY W. EVANS, civil engineer, for many years a member of the firm of Sparks & Evans, Philadelphia, Pa., died Sept. 3 at his home in Merion, Pa. Mr. Evans was a graduate of Dartmouth College in the year 1871.

MANUS MCHUGH, contractor, Philadelphia, Pa., died in that city Sept. 9 at the age of 69 years. Mr. McHugh was born in Londonderry, Ireland, but came to this country in infancy. He had for nearly forty years held municipal contracts for Philadelphia and had constructed many bridges in and near the city.

LANGDON GIBSON, who until two years ago was production manager of the General Electric Co. and had been associated with that company for 31 years, died Sept. 5 at Cribhaven, Maine, of cerebral hemorrhage. Mr. Gibson was 58 years old. He was one of the members of the Stanton expedition through the Grand Canyon of the Colorado in 1889 and also accompanied Admiral Peary on his second northern expedition.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

More Motor Vehicles Mean Continued Road Program

Steady Market for Equipment Indicated
by Registration of 13,002,427 and
Revenue of \$200,000,000

For manufacturers of road-building equipment and materials figures on the registration of motor vehicles in the United States for the first six months of 1923, showing a total of 13,002,427 passenger automobiles and trucks, as against 12,238,375 for the entire year of 1922, are significant in indicating the need for a continuing program of both road construction and maintenance. The statistics are contained in a report just issued by the U. S. Bureau of Public Roads, which leaves the Good Roads Board of the American Automobile Association to the conclusion that neither the United States nor any of the individual states are approaching the saturation point in number of motor vehicles in use.

The increase in number of motor vehicles in the United States has continued at approximately the same rate as preceding years, states the Good Roads Board. In the states leading in numbers of motor vehicles where the road programs are also in advance of the other states, and where the first indications of approach to the point of saturation might be expected, the percentage of increase has kept pace and in some instances has outdistanced the records of the Southern states where the road programs are in course of development.

TRUCKS SHOW GAIN

An interesting deduction gathered from the report is the marked increase in numbers of motor trucks for the six months' period as compared with the entire year of 1922, indicating the rapid growth of the use of the motor vehicle for commercial purposes. The truck registration is 1,371,058, an increase of 92,254 since January 1.

In all but nine states, material increases were shown in number of motor vehicles registered during the six months' period of 1923 over the entire year's registrations of 1922. With six months yet to go the record of 1923 in all states will exceed that of 1922.

The State of Ohio climbed up to second place in total number of motor vehicles registered, changing places with California. New York again leads with a total registration during the six months period of 1,025,718 motor vehicles. Ohio is second with 965,000 and California third with 933,808. Pennsylvania is fourth with 922,062; Illinois fifth with 833,920; Michigan sixth with 624,590 and Texas seventh with 571,981. The total number of motor vehicles registered in all of the states during the six months period was 13,002,427 as against 12,238,375 for the entire year of 1922.

The total revenue from registration was \$167,240,937.76 for the first six

Road Equipment Exhibitors Must Be Association Members

At a joint meeting in Chicago, Sept. 7, of the board of directors of the Highway Industries Exhibitors' Association and Charles M. Upham, recently appointed manager of next year's Good Roads Show and convention of the American Road Builders' Association, a decision was reached requiring all exhibitors at the next show, to be held at the Coliseum, Chicago, Jan. 14-19, to be members both of the Highway Industries Exhibitors' Association and the American Road Builders' Association. A clause covering this requirement will be inserted in the contracts for space at next year's Good Roads Show. According to the terms of the resolution passed, it also becomes necessary for present members of the exhibitors' association who are not members of the road builders to join the latter organization.

The meeting of directors, representing manufacturers of equipment and materials which will constitute next year's exhibit, was characterized by complete harmony and pledges of co-operation between the exhibitors and the road builders. Mr. Upham announced that the floor plan of the Coliseum has been rearranged to provide better facilities and more space for exhibits. In addition, a larger entrance from the Coliseum Annex into the adjoining Greer building will be provided.

Cast-Iron Pipe Production

Based on returns from 12 establishments, statistics on the production, orders, sales and shipments of cast-iron pipe have been issued for the first time by the Department of Commerce. The figures cover the month of June and are as follows:

Production, 81,208 tons; shipments, 88,318 tons; orders to be shipped from stock, 17,905 tons; orders to be made on orders, 199,271 tons; orders not specified as to sizes, 4,366 tons.

months as compared to \$152,047,823.74. In addition to the revenue from registrations the states collected from the motorists \$8,669,174.03 in taxes on gasoline during the six months period of this year, as compared to a total collection of \$11,923,442.61 for 1922. As the gasoline tax is collected as the fuel is used, the record for the year 1923 may be expected to double that of 1922. The gasoline tax in some of the states did not go into effect until late in the year.

The final record for 1923 will indicate that motorists will have paid direct taxes in registration fees to the states and gasoline taxes approximately \$200,000,000, according to the Good Roads Board of the A.A.A. This will not include the personal property tax or special registration or gasoline taxes imposed by cities, counties and townships.

American Lumber Manufacturers to Send Commission to Japan

Fifty thousand dollars was appropriated Sept. 1 by the Douglas Fir Exploitation & Export Co., as a cash contribution for Japanese relief, according to a telegram from Seattle to the National Lumber Manufacturers Association, Washington, by Edgar P. Allen, its director of public relations, who has been in San Francisco, Portland, Tacoma and Seattle for several days in conference with West Coast lumbermen in regard to their co-operation in meeting the Japanese crisis. In addition to the cash contribution the association expects to spend \$50,000 more in providing technical, executive and administration assistance in rebuilding the devastated regions. Furthermore, the individual lumbermen and sawmills of the West Coast are making contributions to the Red Cross fund and every precaution will be taken to hold down lumber prices for the Japanese and prevent profiteering. The Douglas Fir Exploitation & Export Company is an export association of more than one hundred lumber manufacturers of the Pacific Coast. It is largely through this company that the individual manufacturers transact their ordinary export business with Japan.

In the matter of practical assistance the export company plans to send a commission of lumber experts and building advisors to Japan at once, with the consent and approval of the United States Government. This commission hopes to overcome the chief immediate difficulty in meeting the Japanese emergency demand for lumber, in that it has not been their custom to accept American grades and sizes but have imported according to their own specifications which necessitate special orders.

It will be one of the purposes of the lumbermen's commission to instruct Japanese builders in the use of commercially standard American products in order that full supplies of materials may be furnished without delay. It is believed that the commission of lumber experts will be able to sail to Japan within the next thirty days and in all probability the work abroad will require at least three months of the commission's time.

Shows Way to Make Better Lime

Experiments conducted at the Bureau of Standards have shown a way to improve the manufacture of hydrated lime so that the grade known as "finishing" hydrate is regularly produced instead of the grade known as "masons'" hydrate which, because of its lesser plasticity, commands a lower price. These tests have shown that plasticity depends not alone upon the colloidal content of the hydrate, but upon the effect on this colloid of the manufacturing process. The colloid, like glue, must not be allowed to dry out during the manufacturing process, and it must also be prevented from flocculating itself when the mixing water is added preparatory to use.

It has been found that the drying out can be prevented by letting the freshly made hydrate cool in an atmosphere of steam, while flocculating can be prevented by adding small amounts of a readily soluble calcium salt. A hydrator designed to apply these principles has just been completed for further experiment.

Foreign-Made Brick Appears in American Market

For the first time during the business career of anyone now manufacturing brick, according to the monthly statement issued Sept. 1 by the Common Brick Manufacturers' Association, Cleveland, some competition is felt from foreign-made brick. This is apparent so far, the association states, only in the New York market, where considerable quantities of brick from Germany and Holland are reported to be coming in. It is stated that these brick can be purchased on board ship at German and Holland ports for \$4 a thousand, and that American manufacturers cannot compete with this low production cost even after transportation and handling on this side of the ocean has been absorbed. This competition, the manufacturers believe, is not likely to reach far inland, but would affect Atlantic ports unless the American manufacturers in those locations find some protection. American made brick still is claimed to be preferred by the builders in New York and is in ready demand even at a higher price than the foreign made brick.

Cost Accounting Suggestions for Trade Associations

A pamphlet dealing with the acceptance and installation of uniform methods of cost accounting by the members of a trade association has just been issued by the Fabricated Production Department of the Chamber of Commerce of the United States. The pamphlet is designed to "be of assistance to the officers and members of those trade associations which have undertaken to secure the numerous and important advantages of such uniform methods."

The first part of the text is devoted to the ways and means by which the trade association's service to its members may be made the most effective. It deals with such matters as the organization of an association cost bureau and cost councils, and provisions for keeping the members informed of developments generally. The second part is designed to be of direct and substantial value to the president, the general manager, the auditor and other executive heads of the various member companies. It suggests some of the preliminary steps that may well be taken in order to make sure that the association's uniform cost accounting methods are put into use most effectively.

New Manufacturing Plant Opened by Sullivan Co.

Manufacturing began last month at the new western works in Michigan City, Ind., of the Sullivan Machinery Co., manufacturers of compressors, drills and other mining and quarrying machinery. The new buildings were completed some time ago, and during the past month the machinery and equipment have been moved from the company's old plant at Chicago to the new quarters. The new plant is designed for the manufacture of air compressors, diamond core drills, drill steel sharpening machines and cutter bit sharpeners. The new buildings are one-story, and equipped with all modern appliances for manufacturing and handling the product rapidly and at

low cost. The plant is served by the Pere Marquette R.R. With these facilities, which will give an initial manufacturing capacity double that of the old works at Chicago, the company announces that it will be able to meet the increased demands from its field and to serve its customers to much better advantage than heretofore.

The general office force and officials of the company, members of the board of directors, the company's bankers, railway officials and others spent a day at Michigan City inspecting the new plant. Addresses were made by Frederick K. Copeland, president of the company since its consolidation in 1892; the president of the Chamber of Commerce of Michigan City and others.

Business Notes

PAWLING & HARNISCHFEGER Co., Milwaukee, builders of traveling cranes, hoists, lumber handling cranes and excavating machinery, announces the appointment of N. B. Norris as manager of its New Orleans office. The company has also opened a new office in Detroit, with James Van Buskirk in charge.

SOUTHERN PINE ASSOCIATION, New Orleans, announces the closing on Sept. 1 of its regional office at Jacksonville, Fla. This action, Secretary-Manager H. C. Berckes states, is in line with the policy of the association not to maintain any regional offices in Southern pine producing territory. The association, however, through the New Orleans headquarters, will continue to render such special services as may be required both to Georgia-Florida subscribers and to those in all other sections of producing territory, as the needs arise.

H. T. GARVIE, chief engineer and general manager of the British Steel Piling Co., London, will arrive in America Sept. 20 for a three weeks' visit. His address will be McKiernan-Terry Drill Co., 15 Park Row, New York City, for whom his company acts as selling agents for all countries outside North America. The British Steel Piling Co. first introduced steel piling in Great Britain 16 years ago and is interested in the representation in Europe and British Colonies of contractors' plant generally, but principally the small tilting-drum concrete mixers, steam shovels, guy derricks, tar macadam plants and similar equipment.

D. F. HOLTMAN, construction engineer of the National Lumber Manufacturers' Association, returned to Washington Aug. 27 after a summer in the West visiting logging and lumbering operations. He was with a party including W. A. Gately of the Department of Commerce, who was making a survey of waste prevention problems and possibilities for report to Secretary of Commerce Hoover; E. P. Ivory of the Forest Products Laboratory, whose special mission was a study of lumber grading problems; and J. E. Jones, Chief Inspector of the Southern Pine Association. C. J. Hogue of the West Coast Forest Products Bureau, arranged the itinerary and accompanied the party.

STONE & WEBSTER, INC., Boston, has opened an office in the Leader Building, Cleveland, Ohio, in charge of J. R. Hammond, district manager of construction and engineering.

Equipment and Materials

Mechanical Loader Designed for Handling Snow

Changes in its elevating conveyor have recently been made by the Barber-Greene Co., Aurora, Ill., to adapt this type of equipment to the loading of snow into trucks. The crawler-mounted chassis of the standard sand or stone

loader is retained, but the new feature is the loading boom which, instead of carrying an endless chain of buckets, is equipped with a continuous wide rubber belt. The design of the receiving end of the conveyor also has been altered to provide for wide scoops to gather in and feed snow to the moving belt. The discharge end of the conveyor is provided with baffle plates to deflect the snow to one side or the other.

The overall length of the snow loader is 28 ft., maximum height 12 ft. 9 in., plowing width, 6 ft. 6 in., and weight 12,200 lb. The rated capacity of the equipment is 5 cu.yd. per minute. The inclined loading boom is carried on a chassis with crawler treads driven by a four-cylinder Buda gasoline engine. The machine has four speeds, three forward for loading of 30, 60, and 120 ft. per minute, and one reverse, of 35 ft. per minute.

There are two plows or scoops, one on each side of the conveyor belt, which are fitted with hardened steel scrapers and may be adjusted in height with relation to the pavement surface so as to pass over such obstructions as manholes. The conveyor is a four-ply rub-

ber belt, 32 in. wide, with cross-angle flights every 20 in. and is flanked on either side by 12-in. skirtboards to increase its carrying capacity.

On city streets the load can best be utilized in picking up snow which has been pushed by plows toward the gutters. To date more than twenty of these machines have been placed in service by municipalities or street railway companies. The machine can be utilized the year round by exchanging the snow-loading boom for the bucket conveyor boom designed for handling sand, gravel and coal.

Coat Water Pipe With Asphalt from Pressure Distributors

Applying asphalt as a protective coating to water pipe with equipment designed to spread asphaltic oils on roads was the method recently employed by the Los Angeles water department. The work in hand was the coating of 1,500 ft. of 14-in. conduit near the corner of La Brea and Third St., Los Angeles, and was in charge of Thomas Brooks, assistant superintendent of the city water department. Hitherto all such coating had been done by hand with brushes and buckets. Mr. Brooks decided to utilize the large motor truck pressure distributors of the A. F. Gilmore Co., oil producers and refiners of Los Angeles, to apply the asphalt by spraying.

Part of the equipment of these trucks is a metal hose leading from the tanks. It was a simple matter to lengthen the hose and attach. As in the case of oils for road building, the asphalt was heated to the required temperatures at the refinery, loaded into the truck tanks there, hauled to the job and maintained at that heat. The job was completed by three men within seven hours.

PRESSURE DISTRIBUTOR WHICH DELIVERED ASPHALT TO HOSE LINES AND SPRAYS FOR COATING PIPE

Publications from the Construction Industry

Gasoline Locomotives—FATE-ROOT-HEATH Co., Plymouth, Ohio, has published a 31-p. bulletin illustrating the uses of its gasoline locomotives on a variety of heavy construction work. Photographs and explanatory text relating to jobs on which Plymouth locomotives were employed for hauling materials include dams, bridges, dry docks, stadiums, canals, power plants, industrial buildings, filtration plants, subways, aqueducts, and tunnels.

Snow Plows—GOOD ROADS MACHINERY Co., INC., Kennett Square, Pa., features its Champion snow plow in a 31-p. illustrated pamphlet just issued. The plow is designed for attachment to the front end of a motor truck or tractor and consists of a steel scraper blade 10 ft. long and 20 in. wide. The blade may be set at any angle to the line of travel and a lifting device permits the scraper to be raised by the operator. The company manufactures also the Climax snow plow, which is a special adaptation of its road grader for snow removal work. This machine consists of a steel scraper bar attached to a semi-circle and swung under a frame that is carried by a four-wheel truck.

Water Filters—GRAVER CORP., East Chicago, Ind., explains in a 12-p. illustrated bulletin the features of its horizontal pressure type water filters. They consist of a cylindrical steel shell with a manifold and strainer system underneath filtering material of crushed quartz and graded gravel. These filters operate according to the mechanical or rapid sand method and are built in six sizes, all 8 ft. in diameter and ranging from 10 to 24 ft. in length. The process involves the use of a coagulant whose application is regulated automatically by a differential pressure tube. The filters may be operated as single units or, where larger capacities are demanded, in batteries of two or more.

Brass Pipe—BRIDGEPORT BRASS CO., Bridgeport, Conn., presents in an attractively prepared 47-p. illustrated booklet information to assist architects, engineers, builders, plumbers and owners in obtaining the maximum value for a given expenditure for brass pipe as a means of eliminating expense and damage due to corrosion. The text contains a great deal of valuable technical data on corrosion of steel, wrought iron, cast iron and brass pipe. A number of pages are devoted to the manufacturing processes which the company employs in the production of its Plumbrite brass pipe including the composition and mixing of material, pouring, piercing, drawing, annealing and testing. Useful suggestions are offered on the selection of sizes of brass pipe for plumbing installations in large buildings. Practical hints are given, also, on cutting threads in brass pipe, cutting pipe, and making joints and bends. The text concludes with a discussion of items of cost in a piping system for hot and cold water service. The company points out that the data in its booklet have taken two years to collect and it is believed that the practices outlined and recommended are representative of the best in use today.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Record Cement Production During August

Production of portland cement in the United States in August totaled 12,967,000 bbl., shipments were 14,971,000 bbl. and stocks at the end of the month were 6,077,000 bbl., according to statistics of the Department of the Interior, prepared by Ernest F. Burchard of the Geological Survey and based mainly on reports of producers. Last month's production exceeded that of the same month in 1922 by 1,303,000 bbl.

For the first eight months of this year production has been 87,907,000 bbl. as against 70,139,000 for the same period last year, or a gain of 17,768,000 bbl. Shipments for the first eight months of 1923 were 90,909,000 bbl. compared with 76,240,000 bbl. for the same period in 1922.

August production and shipments are greater than in any month thus far recorded and stocks are higher than in August last year.

Public Bond Sales Continue Dull During August

The dullness in the bond market, so noticeable in July of this year as compared with previous years, continued during the month of August. The aggregate of the bond disposals for August, according to the *Commercial and Financial Chronicle*, is only \$49,750,564, as against \$69,375,996 in August, 1922. Not many issues of one million dollars or over figured in the awards for the month the present year. The state of California put out \$4,000,000 41-per cent highway bonds; Rapides Parish, La., issued \$2,000,000 5-per cent road bonds and Crawford County, Pa., issued \$1,000,000 41-per cent road bonds.

The number of places in the United States selling permanent bonds and the number of separate issues made during August, 1923, were 340 and 474, respectively. This contrasts with 387 and 561 for July, 1923, and with 537 and 701 for August, 1922.

Of the 44 representative bond issues included in the accompanying table four were sold at par, three below and the remainder above par. The yields ranged from 4.20 to 5.99 and the rate of interest from 4 1/4 to 6 per cent.

Immigration Statistics on Labor in Construction Industry

Immigration statistics recently made public by the Department of Labor and presented to its members by the Associated General Contractors of America give facts concerning the number of aliens entering the country who may be considered as potential additions to the ranks of construction labor.

The figures show that a total of 522,919 immigrants were admitted to the United States during the last fiscal year as compared with 71,450 aliens who emigrated from the United States during the same period. Of the immigrants 307,522 were men.

A list of occupations of the immigrants includes the following: Carpenters and joiners, 12,305; iron and steel workers, 4,076; painters and glaziers, 2,550; plumbers, 1,197; metal workers, 764; masons, 3,276; stone cutters, 521; tinners, 512; mechanics, 4,644; blacksmiths, 2,296; and laborers, 83,552.

More carpenters and joiners came

into the country than men following any other single line of skilled work, the next closest total being that of 5,559 tailors.

Lumber Movement Declines

According to reports to the National Lumber Manufacturers Association received from 387 of the larger commercial lumber mills of the country, the national lumber movement declined considerably in the week ending Sept. 8, although substantially larger than for the corresponding week of 1922. The 131 reporting mills of the West Coast Lumbermen's Association and the 129

reporting mills of the Southern Pine Association, however, showed an increase in unfilled orders from 548,820, 147 to 563,574,584 ft. For all the mills shipments were 81 and orders 82 per cent of production. For Southern Pine mills these percentages were 83 and 89 and for West Coast mills 87 and 96.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 159 to 171, are the following:

Apartment, Brooklyn, N. Y., Kraslow Building Co., Inc., \$1,500,000.

Bank and office, Cleveland, O., Brotherhood of Locomotive Engineers, \$5,000,000.

Transmission Line, Timmins, Ont., Hollinger Consolidated Gold Mines, \$1,000,000.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 159 to 171, are the following:

Office, Dallas, Tex., to Watson Co., \$5,000,000.

Office, Los Angeles, Calif., to Foundation Co., San Francisco, about \$1,500,000.

Road, Florida, 7,121 mi., to C. F. Lytle, Jacksonville, \$252,357.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual biddings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Sept. 6; the next, on Oct. 4.

Explanation of Prices—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given; 45-5% means a discount of 45 and 5 per cent. Charge is 15c per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b.

Labor—Concrete laborers' rate, 93¢c.; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu.yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars. Other materials delivered.

San Francisco quotes on Heath tile, size 51 x 8 x 3. Prices are all f.o.b. warehouse except C. L. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 97.5¢). Bag charge is 80c per bbl. Discount of 10c per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$17.42; 6-in., \$119.

Changes Since Last Week

Raw linseed oil is quoted in Dallas at \$1.04 per gal. (5 bbl. lots) as against \$1.10, and at \$1.09 in San Francisco, compared with \$1.16 per gal., one week ago.

Common labor is being paid 35¢@40c. in Montreal as compared with the former rate of 30c. per hr.

The iron and steel situation, briefly, is as follows: Pig-iron market tending downward since settlement of coal

strike. Furnaces piling iron, preparatory to going out of blast until demand improves. Structural very firm at \$2.50 base. Car material demand strong and plate shipments improved. Structural demand also increased, principally for schools, commercial and residential buildings and bridges. Bars stronger; buying active, particularly in cold-finished material. Bulk of present business in sheets and tin plates.

This week's market is characterized by a slightly firmer tendency in lumber. Minneapolis reports an advance of \$2 per M. ft. in Douglas fir, while the other eight cities reporting weekly to Engineering News-Record, show decided firmness in lumber prices.

Black steel pipe also firmed slightly in Montreal and Dallas while lime quotations dropped somewhat in the latter city.

Volume 91

NEW YORK, SEPTEMBER 27, 1923

Number 13

Local vs. National Society

THE decline of one-fourth in the membership of the New England Water Works Association in the past seven years, mentioned in the address of the retiring president last week, must be a matter of concern to the officers and others who have the welfare of the organization at heart. It is true that the 769 members as of Sept. 1 is a goodly number for an association which recruits its ranks chiefly from a small section of the country; but the members could once truly say that the "New England Water Works Association is local in name only." It is still largely true. That it is not so markedly true now as formerly is due in part to the strenuous efforts of recent years to make the American Water Works Association a large and thoroughly representative national organization, with sectional branches, both geographical and technical. Perhaps men who are members of both organizations have put so much of their time and strength into the American Association for the past few years that they have unwittingly robbed the New England Association. The situation deserves careful study by all the friends and supporters of both organizations, for neither is going to gain materially and permanently through the decline of the other.

A Construction Safety Code

DISCUSSION of the proposed safety code for construction work, which will be taken up by the Construction Section of the National Safety Council at the meeting next week in Buffalo, N. Y., should be active. Following factory practice, construction organizations have in a few years made remarkable progress in accident prevention. In the beginning the effort was largely individual and it is still confined too largely to a comparatively small number of progressive constructors. Group effort was made possible by the organization six years ago of a construction section of the National Safety Council and, although the work of the section has been handicapped by inadequate support by builders and general contractors, it has, with a few loyal members, done much good. This year's meeting should witness a change. Contractors should become members. The expense is small, the encouragement to a good object will be great, and the benefits derived through the service of the national council will repay all the efforts and money expended. It is particularly timely to join in the section work now that the American Engineering Standards Committee is formulating the comprehensive safety code just ready to be presented for discussion and revision. In this code the engineering contractor has for the first time a manual which will guide him and his superintendents and foremen in planning the safety measures best suited to the particular operations in which he is engaged. Indeed it is wisely the purpose of the code not to give the builder or the sewer contractor a "set of rules" to nail

to his field-office door. Full accident prevention efficiency is had only when the superintendents and foremen are induced to do constructive thinking in devising safety measures. Knowing the sources of danger, which it is the duty of the employer to give him, the man who has working crews and specific operations to direct develops remarkable efficacy and constructive pride in devising safety methods.

Keep Cars Full Loaded and Moving

ALMOST every week the railroads are establishing new records for cars loaded, for the average load per car, and mileage per car per month. How much of this improvement in service is due to increased and improved facilities it is impossible to say but it is quite certain that a large part of it is due to efforts of the American Railway Association, spurred on by the expressed public dissatisfaction with the railway service of the past few years. The association's realization of the need of drastic improvements in the service culminated in the inauguration last spring of a movement to improve the car and locomotive performance throughout the summer months in order to have the railroads in the best possible condition for the rush of the fall and early winter. Responsibility for the success of their plan rested largely with the railroads but no small part of it also rested with the shippers and consignees in loading or unloading and releasing cars promptly. There is every indication that both parties have done their part well and that the country would have gone into the rush season with something approaching the required number of cars, but for the three weeks' cessation in anthracite mining. This will increase the peak of the demand for cars in the ensuing months and the railroads will be hard pressed to meet it. The situation is one which requires hearty co-operation with the railroads by everyone who has anything to do with the shipment or loading of freight. It can be met if cars are loaded to capacity, loaded promptly and released as soon as possible after reaching their destination.

Engineering Trail Making

ROAD building in Alaska is pioneer engineering in almost its bleakest aspects. As described by the head of the Alaska Road Commission in this issue, two-thirds of the nearly 7,000 miles of Alaskan roads are trails for dog-teams and pack-trains. The distinction between this trail making and the Wilderness Trail of Daniel Boone or a dozen other historic trails of the pioneer days of America is that the development and maintenance have been under engineering direction. The Indian and the buffalo had more to do with the location of the trail which Boone and his axmen cleared across the mountains than did the engineer. Its maintenance was the concern of no one and least of all did it have the attention of engineers. It is perhaps in the

respect of maintenance that Alaska's 1,500 miles of trails stand out most distinctly. In mentioning trail maintenance nothing of course of the character of road upkeep in the States, even the dirt road states, is in mind. It means little more than that defined trail is made a little more clearly defined and easily traveled each year and is being thus progressively developed into wagon road. With a not much greater yearly expenditure for its whole mileage than many Eastern states have put into a score of miles of paved road construction, the engineers of the Alaska commission are developing a real road system which each year puts a little less hindrance on travel and each year is a little more open to the use of modern vehicles. This is highway engineering of the highest quality from which engineers working under better conditions should not withhold praise.

Inspection From the Outside

IN ONE of our large cities the dealers in reinforcing steel have taken a novel method of improving the practice in reinforced-concrete construction, with the idea that every poorly built structure is a detriment to their business and every well built one an advertisement. They have put into the field a number of traveling inspectors who go from job to job and check up the steel used against the amount called for on the drawings. Some of the contractors have resented this as an unwarranted intrusion into their business but the steel people have been backed up by the owners and engineers and have proved to their own satisfaction that the scheme pays as a preventative against skimpy construction. The idea might well be adopted by the cement companies. It is too true that the rules for good concrete making are not observed by many who should realize their necessity. This includes engineers as well as contractors. An outside agent might well observe infractions which when reported and emphasized would be remedied, though in the routine of construction and inspection they would be passed over. Every poorly built concrete structure is money out of the pocket of the cement industry. That industry is spending great sums to spread the knowledge of how to make good concrete. It might well spend a little more in the wider application of the experiment of "butting in" on specific jobs with a view to specific improvement in practice.

Building Methods Primitive

THERE has been less development of the small labor-saving machine in engineering construction than is to the credit of either the constructor or the equipment manufacturer. Equipment for mass operations, as the steam shovel and concrete mixer, has been advanced far in mechanical perfection and in employment. So have special machines like the trench excavator and the paving mixer. It is in machines for individually small operations that development has lagged. Building construction, which is pronouncedly a series of non-continuous processes of great variety, furnishes a particularly good example. Except for the high development of pneumatic tools in steel erection, we find very few light-task, labor-saving machines used. Carpentry, plastering, painting are, most commonly, hand operations on large buildings and are always manually performed in residence and other small building work.

Why should acres of plaster in a modern large office or commercial building be put on with hand trowels and other acres of painting be a pail-and-brush operation? Why should yards of concrete floor be laboriously smoothed with hand floats? It is not beyond inventive skill to devise usable tools. Indeed we already, it would appear, have the elements of successful tools in the cement gun, the sand blast, the paint sprayer and the wooden floor finisher.

All the backwardness does not, however, lie with the equipment manufacturer. Neither the contractor nor the artisan has progressed much beyond primitive thought in conducting many building operations. It does not seem possible for them to project their imagination beyond the hod and trowel in plastering or the bristle brush as a means of applying paint. Perhaps this is provocative speech, but that is exactly what the building contractor and his workmen deserve. In speaking publicly recently of his industry one of the most prominent building contractors of the country said: "In the building industry alone, among leading industries, primitive methods still prevail." Again he said: "The high cost of building is traceable to the lack of progress in the building industry toward developing improved methods." Indeed a little more ingenuity exercised by builders in devising new machines and methods and a little less in inventing subterfuges for constructive thinking would greatly help present building conditions.

Specializing by Proclivities

DURING this season thousands of young men are entering our engineering schools, there to start or to renew a task which each expects will lead him to eminence in the engineering profession. Fortunately for them, perhaps, they are not much concerned with the efficacy of the courses which are laid out for them to pursue. They want to become engineers, and having selected from a narrow choice the particular kind of engineer they want to be, their job is merely to complete the provided program to the best of their ability. The profession—and the educators—know that the problem is not so simple; that engineering has diversifications not at all expressed in the diversifications of the college courses, and that not a few of the troubles of the engineering profession are due to the misfits who are in it. How best to fit the individual proclivities to the prospective job is one of the most engaging problems ahead in engineering education.

Two opposing methods of doing this should be noted. One is in practical operation in many universities; the other is only a proposal. The actuality is a growing tendency toward a basic course which comprises the fundamentals of engineering and through which all varieties of engineers must pass. Having concluded this, the individual by that time trained in thought and competent to judge his own proclivities and capabilities, may select the specialty which he is to follow either in post-graduate school or in the harder school of experience. The proposal is the one made at the Ithaca convention of the Society for the Promotion of Engineering Education by Professor Bennett, of the University of Wisconsin. This suggests a functional division of engineering courses to take the place of the present industrial divisions. Instead of training a boy to be a civil, an electrical, or a mechanical engineer,

direct his studies toward the functional divisions of engineering — research, design, supervision, management, sales. While all of these would have necessarily a certain few fundamentals in common, the type of instruction would vary with the type of activity to be followed.

Each of these methods recognizes the difference in individuals and endeavors to prevent the errors which result from fitting square pegs into round holes. The distinction is that the one basic course depends on a system of natural selection, while the functional courses depend upon some artificial method of predicting the individual's bent. As the science of psychology stands today, the former seems more reliable. At some future time the psychologist may be able to solve this problem for us. It may be possible by some system of test to determine what bent the individual boy should pursue—whether he will make a better salesman than a bridge designer, or a better manager than a testing engineer. That day is far off and when it comes, if ever, there will always be the right of free individual choice to counteract some of its benefit. Professor Bennett recognizes, we think, these difficulties, not only in the exact assignment of subjects to meet his requirements, but more especially in the determination of proclivities. But the growth and development of engineering make such a proposed system of instruction most attractive and worth studying. Certainly, if there is any way of ascertaining what the boy should do, either of the two schemes should turn out more definite minded engineers than the current scheme of accepting a boy for study in some industrial branch of engineering with the details of which or the requirements for which he is only vaguely acquainted.

A further opportunity for specialization of training exists in the lower ranks of engineering. There is a great deal of such engineering that does not require four years in a technical school. Many men who cannot afford that much time or the money it entails would be just as well fitted for the practice of this kind of engineering by shorter and more specialized courses. They would be satisfied to spend their lives in the practice of what to other men who have greater ambition or capabilities would be drudgery. The man and the job would be fitted together to the satisfaction of both, and the man who with elementary training rose above the elementary job would be just that much ahead. Much of the current discontent with engineers pay is justified but there are many so-called engineers who are doing work that does not call for higher engineering ability and who are not entitled to any greater reward than they receive. Either they should never have gone into engineering in the first place—many a good bricklayer is running a transit—or they should have gone into it with a limited training which would not have promised them more than their capabilities could fulfill.

There are those engineers who see in the few short term schools that exist a menace to the profession. Properly used they are far from that. If they do not promise to turn out a professional engineer, one competent by his training to rise to any engineering responsibility, they serve a very useful purpose and should be encouraged because they may help to do what should be the ultimate aim of all engineering schools—to provide instruction in accordance with and in proportion to the student's proclivities.

Moral Suasion to Cheapen Coal

THERE is no simple solution of the problem of producing coal at fair prices, for fair wages and at a fair profit. That is the conclusion of the final report of the now defunct Federal Coal Commission. After eleven months of strenuous endeavor and after spending over half a million dollars the best the commission can do in the way of remedy is to suggest certain procedure on the part of the government, the industry itself and the public which, it is hoped, will in time cure the complicated disease that hampers all industry and disturbs every citizen. The essence of the conclusion is that it will take time to effect a cure. In the process the government must relax its inhibition on industrial combination and must insist on the public recording of statistics of production and cost, the industry must reform its methods of doing business at least to the degree of making its worst members conform with the practices of the best, and the public must learn to use anthracite substitutes and as a local issue control the cost and mechanics of distribution.

That the report will be disappointing to the public at large cannot be denied. It has been hoped that somehow the commission would find a direct way of preventing the rising cost of fuel and the recurring controversies that spell shortage. It is evident from the voluminous chapters of the report already issued that the complications of the problem are so great that the six men making up the commission can come to no agreement either as to specific blame for the past or specific improvement in the future. Anyone reading those reports will appreciate the difficulties in reaching a decision but the fact remains that the public wanted a decision and will be disappointed that none has been made.

To use the vernacular, the report hasn't the punch. It preserves a fine impartiality of view which was most necessary for the ascertainment of fact but which is most trying when expressed in the excessive verbiage of the conclusions. A few stronger expressions of opinion—even though they had to be divided—would have gained for the report the publicity which now it probably will never receive, and in that respect it will fail in one of the principal things it purposes to do, that is to teach the public how it can prevent future disturbances in the coal industry.

On the other hand the report will probably have a salutary effect on the industry itself. Provided Congress agrees with the commission, the industry will hereafter keep open books and will be taxed out of its excess profits, it will have available a mass of information regarding itself of unprecedented volume and accuracy and, best of all perhaps, it will be forced by fear of future government action to clean house, knowing full well that the dirtiness of that house is now a matter of public information. These are, to be sure, merely moral impositions, so that we will be able in the next few years to see to what extent moral suasion can control a private business which, as the commission points out, economically affects the public interest though the legality of such an assumption may well be questioned.

The net result of the work of the commission will be that for some years the coal industry will continue to have the public at its mercy. That, we repeat, is a disappointing end to a promising beginning, however much that end was inevitable.

Constructing Mitchell Dam on the Coosa River

Electric Traction on Narrow-Gage Tracks—Eight-Inch Stones Run Through Concrete Mixers—
Unusual Supports for Deck Forms—Complicated Forms for Hydraulones

BY L. V. BRANCH

Resident Engineer, Alabama Power Co., Verbena, Alabama

MITCHELL DAM is the second large development of the Alabama Power Co. on the Coosa River, in Alabama. The first development, the Lock 12 plant, placed in service in 1914, operates under a normal head of 70 ft. and has an installed plant capacity of 110,000 h.p. The new plant, here described, is located 13 miles lower down the Coosa River and also develops a 70-ft. head, backing the river up to the elevation of the tailwater of the Lock 12 plant. Other proposed developments will ultimately make use, for power purposes, of practically the total fall and regulated flow of the Coosa River and, by construction of locks at the various dams, will connect the upper navigable section

each, a total of 72,000 h.p., have been installed. The turbines are single-runner, vertical-shaft, concrete casing turbines designed for normal operation at 100 r.p.m. under 70-ft. head, controlled by oil-pressure type governors. The vertical shafts, in 3 sections and 25 in. in diameter, have an overall length of 83 ft. The generators are of 100-r.p.m., 6,600-volt, 3-phase, 60-cycle type and have a maximum rating of 20,000 kva.

The application for a license for this plant under the Water Power Act was filed with the Federal Power Commission on Nov. 3, 1920; the license was granted June 27, 1921, and work was started immediately thereafter on the construction camp, power transmission line to the job and on railroad connection.

The dam has an overall length, including abutments, of 1,264 ft. The average height of the dam, river bed to flow line at El. 350, is 73 ft., and maximum height 89 ft. in one deep, narrow channel. The base width is 74 ft. 3½ in. The spillway, of ogee section, occupies the full width of the river channel and consists of 26 sections each 30 ft. long, with crest at El. 335, separated by bridge piers 6 ft. wide, and 5 sections of emergency spillway, totaling 150 ft. long, with crest at flow line, El. 350. On the 780 ft. of spillway at the lower elevation are installed 26 tainter type gates 15 ft.

high and 30 ft. long. These gates are operated through clutches by individual motors for each pair of gates. The gate operating motors are installed in recesses in alternate bridge piers. These 6-ft. bridge piers are 34 ft. in height, the deck of the bridge being at El. 370, or 20 ft. above flow line.

The maximum flood recorded for this stretch of the Coosa River is 175,000 sec.-ft.

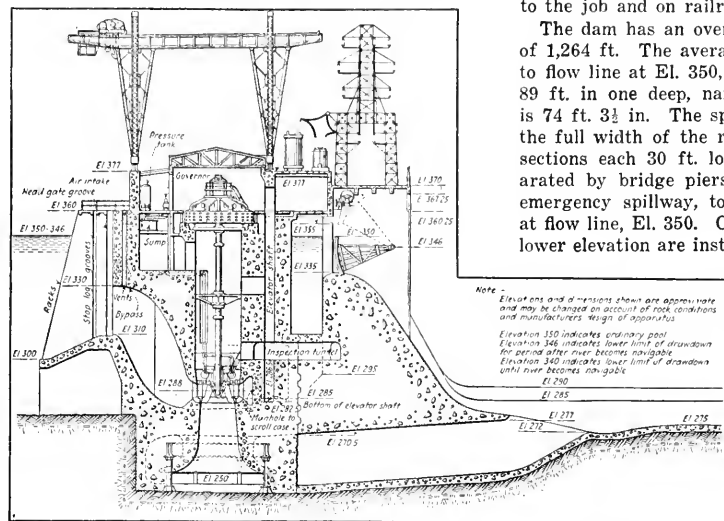

FIG. 1—SECTION THROUGH DAM AND ONE UNIT OF TOWER PLANT

of the Coosa River with the Alabama River, which is now navigable from Montgomery to Mobile Bay.

In this development each unit of the power plant is located in a separate concrete tower placed upstream from the dam. This design, shown in Fig. 1, results in very short penstocks but comparatively long draft tubes. These draft tubes, passing under the dam, discharge at the downstream toe. Surplus water, during flood periods, passing over the dam removes the high tailwater from over the draft tube discharge openings, thus increasing the effective head on the plant. This "backwater suppressor" was described by J. A. Sinit, designing and electrical engineer for the Alabama Power Co., in an article in *Engineering News-Record*, June 8, 1922, p. 966.

The plant is designed for four units of the suppressor type and for one unit of the conventional type to be located at the west end of the dam, a total ultimate installation of 120,000 h.p. At present foundations have been constructed for four units. Three of 24,000 h.p.

This flood can be passed at Mitchell Dam by operation of the spillway gates, without raising the pond level. The dam is designed for maximum high water 4 ft. higher, that is, with 19 ft. of water over the main spillway and 4 ft. over the 150 ft. of emergency spillway. At this stage 300,000 sec.-ft. will pass the dam; a flow of 30½ sec.-ft. per square mile for the 9,827 sq.mi. of catchment area.

The dam contains no sluices. Fig. 1 shows normal section of spillway and section through power house.

Railroad Connections—The site of the dam is about 33 miles due north of Montgomery and within 7 miles of the main line of the Louisville and Nashville R.R. running between Montgomery and Birmingham. Railroad connections with the L. & N. R.R. were made at Coopers station where yards with suitable switching tracks and storage tracks for 40 cars were constructed. Track scales were installed at this terminal and two warehouses, with a combined capacity of 7,000 bbl. of cement, were erected.

FIG. 2—ASSEMBLING FORMS FOR DRAFT TUBE OF UNIT

The railroad to the dam had a main line length of 8 miles, with an additional mile of spur tracks at the dam. These standard-gage tracks at the dam extended past the warehouses and cement and sand storages to a point under the cableways at the west end of the dam at high level, and the line was later extended out on the bridge over the dam, and to the quarry. It did not reach the river level at the dam site, for all construction tracks on the low level were narrow gage.

Camp—On account of the distance from the job to the nearest towns, it was necessary to provide camp accommodations for practically the full force required by the work. During the period when the maximum force was required, the camp had a population of 2,000.

The power company owned about a square mile of land at the west abutment of the dam. This area was a series of sharp ridges, separated by draws leading to the river. These ridges and valleys provided sightly, well drained locations for the segregation of the various sections of the camp, although the rough topography and spreading out of the camp greatly increased the cost of road construction, water supply and maintenance of camp.

The ridge nearest the dam was occupied by the main white camp and service buildings. A higher ridge above this camp was occupied by twenty-four comfortable cottages for white families and a well equipped hospital with normal bed capacity for fifteen patients. The hospital often cared for twenty patients at a time.

The negro camp, covering an area of 32 acres, was separated from the other camps and surrounded by a 10-ft. wire fence to prevent trespassers entering the camp. The gates in this fence were never all locked nor guarded, but they concentrated entrance to the camp at points under easy observation. To care for gangs of new negro laborers shipped in to the job, there were provided a mess hall, bath house and six 24-men bunk houses. For negro families, 20 two-family houses and one hundred and eighty 10 x 14-ft. shacks were erected. All these shacks were equipped with double bed, with spring and mattress, and cast-iron laundry heater. There was always a waiting list of men who wanted a shack for a family, or a group of men who wanted a similar shack as a bunk house. These small shacks proved one of the best investments in the camp facilities. A filtered water hydrant was provided for each group of eight or twelve of these houses. The negro camp was also provided with a billiard hall and a dance hall, for in order to hold large forces of negro labor it is necessary to provide amusement and quarters for the families.

The company sold building materials at cost to white employees who wished to erect small frame houses or tent houses for individual use, provided connection for electric lights and water and handled the sanitary work for the camp without charge. That portion of the camp which will be used by permanent operators of the plant was provided with sanitary sewers. In the balance of the camp the dry closet can system was used, the cans being changed daily or on alternate days, as necessary. Excellent results were secured.

The camp water supply was pumped from the river to a settling tank where alum and soda ash were added when necessary, filtered through gravity sand filters, chlorinated and then pumped to storage tanks. Water samples were taken at frequent intervals and sent to a commercial laboratory for analysis. This water supply plant gave excellent results.

Plant layout—Preliminary studies of plant requirements were based on placing 200,000 cu.yd. of concrete in fifteen months. While this made an average rate slightly in excess of 500 cu.yd. per working day, the progress schedule provided for placing double this

FIG. 3—GENERAL VIEW OF DAM AND BRIDGE

quantity for considerable periods, or a maximum of 30,000 cu.yd. in one month. The rock crushing, mixing and placing plants were designed for a maximum rated capacity of 100 cu.yd. of concrete per hour. The actual maximum rates of placing concrete were 1,743 cu.yd. for a two-shift day, 9,050 cu.yd. for a seven-day week and 35,476 cu.yd. during the month of November, 1922.

For concrete placing, the equipment selected was stiff-leg derricks with 60-ft. booms and two 10-ton traveling cableways. A combination railroad and derrick trestle was erected at the downstream toe of the dam. Three wooden stiff-leg derricks, with 60-ft. booms were mounted as travelers on this trestle. These very satisfactorily covered the main body of the dam. One similar derrick mounted on an extra high traveler proved efficient in reaching the top section of the dam and the bridge piers. Stationary stiff-leg derricks of the same size were erected upstream of each power house unit for work on these units.

Two 10-ton capacity traveling Lidgerwood cableways of 1,530-ft. span were provided for handling concrete forms and feeding those portions of the job not covered by the derricks. The cableways handled practically all of the work on the bridge piers and decks as well as a large portion of the upper part of the power house. The cableways were used on handling rock excavation and concrete in the body of the dam whenever they were not absolutely required on special

FIG. 4—PLAN AND ELEVATION OF DAM
Showing location of future canal locks.

work. When on straight concrete work a cableway carried an average of twelve 2-cu.yd. batches per hour, whereas the derricks had a considerably greater capacity. One derrick placed 220 2-cu.yd. batches of concrete in eleven hours, in addition to 32 cu.yd. of derrick plum stone. This gives the derrick an average of 43 cu.yd. per hour, as compared with 24 cu.yd. per hour for a cableway.

Yard and Plant Railroad—All tracks on the low level (river bottom) were narrow gage, 36-in.; the $\frac{1}{2}$ -mi. track from quarry to crushing plant and main warehouse was of both narrow and standard gage. The decision to use 36-in. gage tracks on the job was based on the use of electric locomotives with a third rail system, cheaper construction costs and lighter units for handling concrete, which greatly reduced the cost of the trestle on the lower face of the dam.

The principal motive power on the 36-in.-gage line was six 8-ton Baldwin-Westinghouse type locomotives, equipped with a steel shoe for sliding connection with a third rail placed 21 in. outside of the running rails. In addition to the contact shoe, each locomotive was equipped with a reel on which was wound about 200 ft. of conductor cable so that the locomotive could operate some distance beyond the end of the power rail. Workmen were protected from the third rail by a guard side board and cover boards.

In general, the electric traction was highly satisfactory on permanently installed tracks, but was a nuisance on tracks subject to frequent moving or where for various reasons the third rail could not be installed on either side of the track, thus making the locomotive dependent on the cable for power connection.

Cofferdam and Steam Control—The unwatering of the dam and power house foundations was handled in three sections. Cofferdam 1 enclosed the foundations for the west half of the dam, including units 1 and 2 of the power plant. This cofferdam, at the outer upstream corner, extended to the edge of a deep channel of the river, which crossed the dam foundation at an angle of 64 deg. with the axis of the dam. This section of the cofferdam enclosed an area of approximately 5 acres,

having a length of 600 ft. and a width, up and downstream, of 400 ft. The average height of the cofferdam was 18 ft. The upstream and downstream arms of the cofferdam consisted of timber cribs rock-filled, sheeted on the outer side, and provided with toe fill of earth and clay. The outer arm, exposed to the swift current of the river, consisted of a double line of rock-filled timber cribs with a clay chamber between the two lines of cribs.

Cofferdam 2 was constructed during the flood season in the spring of 1922, to enclose the east end of the dam foundations; it extended from the east bank 136 ft. to the east edge of the deep channel above mentioned. A clear opening 200 ft. wide, including the deep channel of the river, was left between Cofferdams 1 and 2. This channel was computed to have a capacity of 65,000 sec.-ft. before flooding Cofferdam 2.

The closure cofferdam or Cofferdam 3, crossing the deepest channel of the river and enclosing the foundations for units 3 and 4 of the power plant, was started as soon as the spring floods of 1922 had passed. As the construction of the third cofferdam proceeded, the first two cofferdams were removed and the river was gradually diverted through eight culvert openings left in the west end of the dam and over a 102-ft. spillway gap left in the east end of the dam. These water passages had a capacity of 35,000 sec.-ft. before the third cofferdam was overtopped.

A section of the upstream arm of this closure cofferdam had a maximum height of 42 ft. and as it was all constructed in swift water it presented quite a construction problem. The 36-ft. square cribs of 12 x 12-in. timbers were started on top of the completed cofferdam, then lowered to water surface by crane, and held in position by cables. They were sunk by building up the timber cribs, and were filled with rock after landing on the river bottom. On account of the great depth and swift water, steel sheet piling was used for sheeting this cofferdam instead of the planking and earth used on the other cofferdams.

The pumping equipment used for the cofferdam work consisted of belt-driven and direct-connected motor-driven centrifugal pumps.

As the eight culverts through the westerly end of the dam were lower than the spillway gap left in the east end of the dam, these culverts carried the full flow of the river during low stages of the river. The spillway gap was therefore filled first without any difficulty. The culvert entrances, divided by a central pier into two parts, were provided with a heavy timber gate for each opening, hinged at the top of the opening and held open by cables. The closure of the culverts was made when only four to five feet of water flowed through them by cutting or loosening the clamps on the cables and permitting the gates to drop into place. The culverts were concreted, after the leakage through the gates was reduced to a point where it could be carried in a few small pipes. These drain pipes were grouted later.

Quarry Operations—The coarse aggregate for the concrete was secured by local quarrying and crushing operations. The quarry was located on the right bank of the river one-half mile below the dam. The rock was a hornblende schist found in an almost vertical cliff 130 to 150 ft. high. The quarry was too short (only 280 ft.) for satisfactory operation, but could not be lengthened on account of property ownership at one end

and very heavy stripping at the other. The quarry rock was generally hard and tough, making excellent aggregate, but due to the presence of a few soft seams and some weathered rock at the surface it required washing much of the time.

Primary drilling was accomplished with two No. 4 Loomis Clipper and two No. 3½ Keystone well drills. These drills were operated by 11-hp. and 12-hp. electric motors respectively. Records on over 3,000 ft. of drilling show an average of 9.33 ft. per drill per shift of 10 hours; drilling bits were 5½ in. in diam. The following record of blasting may be of interest:

Pounds of explosive used.....	69,000
18 per cent was 75 per cent gelatin dynamite for the bottoms of holes.	
61 per cent was 60 per cent and 21 per cent was 40 per cent ammonia dynamite for the balance.	
Cu.yd. of rock, solid measure, per foot of hole shot	11.9
Cu.yd. of rock, solid measure, per lb. of dynamite...	1.74
Pounds of powder per cu.yd. of rock.....	0.575

Blasted rock for the crushers was loaded by steam shovel, equipped with a 2½-cu.yd. dipper, in 5-cu.yd.

sand and two sizes of crushed rock; these bins had sufficient capacity to furnish materials for 350 cu.yd. of concrete. All materials were delivered to the mixer bins by belt conveyors.

Cement storage was provided for 3,100 bbl. in bins and 16,800 bbl. in warehouses. An attempt was made to get the major portion of the cement shipped loose and get sacked cement only for the reserve storage in warehouses. All bulk cement shipments were received in good condition. Although a scraper unloader for the bulk cement was provided, the labor crew unloading cement preferred to use shovels to pass the cement to the car door chute leading to the storage bins. Unloading the bulk cement was no more costly, nor more difficult to keep a full crew employed, than with the sacked cement. While there was an initial saving of 5 cents a barrel in the first cost of the bulk cement, the greater saving was in handling and loss of sacks. Only 41,000 bbl. of bulk cement were received, as the cement company had difficulty in loading the bulk cement at the same time it was loading sacked cement.

FIG. 5—CLOSURE GATES FOR STREAM CONTROL, AND BRIDGE PIERS
Showing method of supporting forms for bridge deck.

dump cars, 36-in.-gage, operated in trains of 4 to 5 cars by 8-ton electric locomotives. Derrick plumb rock was loaded by a 15-ton locomotive crane; this crane also helped on moving the quarry tracks.

Crushing Plant—The primary breaker was a 48 x 60-in. jaw crusher, set for a 7-in. opening, driven by a 150-hp. motor. This type of crusher was selected on account of the larger size of rock that could be fed the crusher as compared with a gyratory crusher of equal capacity or cost. The rock was conveyed from the jaw crusher by a 42-in. belt conveyor to a 72-in. x 16-ft. screen over the secondary crushers. The object of this screen was to separate the fines for the sand rolls, 3-in. to 6-in. size and oversize for the secondary crushers, and 6-in. to 8½-in. size to use as mixer plumb rock. The secondary crushers were two 12-in. gyratories, one of the gyratories later being exchanged for a 16-in. crusher.

Mixing Plant and Concrete Materials—Two 2-cu.yd. mixers mixed all the concrete for the job. Erected over the mixer measuring hoppers were bins for cement,

Passing the cement from the bulk bin to the 16-in. belt conveyor caused some difficulty due to the tendency of the cement to flow in waves. After considerable experimentation, it was found that a 6-in. pipe inserted in the bin bottom and discharging close to the belt gave best results. The pipe was closed by a radial gate over the lower end of the pipe. Where loose cement is used in large quantities, it is believed that a weighing machine should be used instead of a measuring hopper, as was done here. On account of the dust, it is difficult to control manually the filling of a box to the same elevation for each batch.

Slag cement was used in the amount of 29,200 bbl. This was used only in the mass concrete to the extent of 0.208 bbl. per cubic yard of the mass concrete. The slag cement was very slow in setting so was not used at all in the reinforced concrete. Long-time tests of mixtures of the slag and standard portland cement showed strengths equal to or greater than those of the straight portland cement tested at same time. The slag cement

FIG. 6—GANTRY CRANE AND 125-TON ROTOR

was very finely ground, so it made an easy flowing, workable concrete. On a volume or barrel basis, it was considerably cheaper than portland cement, but, due to low specific gravity, on a weight basis it was very little cheaper than the portland cement.

Sand was purchased from commercial sand pits and received on the job in hopper-bottom cars. It was dumped into the storage bin, from which it was transported to the mixer sand bin by a 16-in. belt conveyor. This washed bank sand was deficient in the fine sizes, so it was not found objectionable to use the fines from the quarry and crushers as sand.

Derrick plum rock, up to 4 cu.yd. in size, were selected from the draft tube excavations and from the quarry for dropping in the concrete. Only 8,971 cu.yd. of rock were placed in this way. The principal difficulty was to secure the rock from the quarry which was worked primarily for crusher rock. An additional amount of over 8,000 cu.yd. of small plum stones up to 8½ in. in size, was passed through the mixers with the concrete. The amount of reinforcing steel used in the construction of the plant was 1,205 tons. Of the total concrete, 39 per cent was classed as cut-up and required more or less reinforcing steel.

Concrete Forms—The construction of the concrete forms, next to the stream control, was probably the most complicated and difficult problem to be solved.

For the straight sections of the dam, panel forms were used. These panels, designed to be moved by derricks or cableways, were 5 ft. high by 17 ft. 10 in. long. The vertical posts were 6 in. x 8 in. x 8 ft. 6 in., spaced 36 in. apart and lagged with sized 2-in. lumber for 5 ft. height. The post projecting above the form for a distance of 3 ft. 4½ in. supported the next tier of forms. Two ½-in. anchor bolts were used in each post for each 5-ft. lift.

The expansion joints in the dam were spaced 72 ft. apart, except opposite the power house units where the joints were 108 ft. apart. These lengths between expansion joints correspond to two and three spans of the bridge, respectively, for the bridge piers on top of the dam are 36 ft. center to center and all expansion joints come at one side of a bridge pier.

The bridge pier forms were built in large panels 36 ft. long and with three lifts of form for the 34-ft. height of the pier. As the piers were only 6 ft. thick, through bolts were used to hold these forms.

An unusual design of form support was used for the 32 spans of the bridge deck. Four spans of this deck

at the west end of dam were 56 ft. wide in order to make room for the two circuit feeder sections of the substation structure. The next ten spans were 44 ft. wide and supported the bus tie and lightning arrester sections of the substation as well as the railroad track to the plant. The balance of the bridge deck was 32 ft. wide. The bridge deck is of flat-slab girder type reinforced concrete. Most of this deck was constructed after the pond had been filled and water was passing over the crest of the dam. The forms were supported from 30-in. and 36-in. heavy plate girders resting on blocking on top of the bridge piers. Four steel girders were required for the narrower sections of the deck and seven for the wide sections. Timbers 8 in. x 8 in. were suspended by 1½-in. rods and U-bolts under these girders and the bridge floor forms were built up on these suspended timbers.

The forms for the power house units were very complicated as the turbines had concrete casings and the first two draft tubes included hydracone regenerators.

FIG. 7—HYDRACONE REGAINER IN DRAFT TUBE

Fig. 2 shows a view of the hydracone and draft tube forms for unit 2. This form of draft tube required more complicated formwork and more rock excavation than were required for the draft tubes constructed for units 3 and 4 where the hydracone bell was omitted. All these forms for waterway openings were built in the shop in segments and were fitted together in place in lifts much like a set of blocks.

The heavily reinforced beams over the waterway openings required continuous concrete pours of considerable height. The height from the top of the draft tube floor to the generator foundation was 105 ft. This height was divided into four construction stages. The continuous pour from draft tube floor to bottom of turbine casing was 33 ft. high and required 4,200 cu.yd. of concrete. The next stage had a height of 41.5 ft. in which 3,850 cu.yd. of concrete were placed in one continuous pour of 4½ days' duration.

Permanent Plant Erection—Very little could be done on the plant erection until the bridge over the dam had been completed from the west bank out to the power house section. Then the permanent gantry crane was the first equipment needed but its erection rendered one of the cableways practically useless on account of the interference.

This double gantry cantilever crane is designed to handle the heavy parts of the turbines and generators. It covers a side track of the railroad on deck of dam, an erecting space between the machine shop and unit 1

FIG. 8—LOCATION OF CONSTRUCTION TRACKS AND CONCRETE MIXING PLANT

of the power plant and the four power plant units. The main hook has a capacity of 125 tons between crane legs and a capacity of 70 tons, on both cantilevers, at a distance 13 ft. outside of legs. The auxiliary hoist has a capacity of 20 tons. The upstream cantilever of the gantry covers the trash racks, stop logs and penstock gates while the downstream cantilever covers the 7,500-kva. transformers located outdoors on the roof of the operating room.

The erection of the gantry crane was completed on the last day of January of this year and it was immediately placed in service on the erection of the first unit of the power plant. The first unit was put in service, on the line, on April 7, followed by the second 24,000-hp. unit on May 25. The third unit was placed in service during August.

The elapsed time from the beginning of the work to the placing of the first concrete was 187 days; to the final closure of the dam and filling of pond, 545 days; and to the completion of the installation of the first power plant unit, 621 days. The entire project will be completed and in operation within 25 months from the date that the license was granted to the Alabama Power Co. by the Federal Power Commission.

The turbines were built by the Allis-Chalmers Co., and the generators by the General Electric Co. The construction work was done by the Dixie Construction Co., a subsidiary of the Alabama Power Co.

O. G. Thurlow, chief engineer of the Alabama Power Co., was in charge of the work, and was also the originator of the backwater suppressor used.

Modern Engineering to Save Mediaeval Tower

Reinforced concrete is to be used to prevent the collapse of the great tower of the Strasbourg Cathedral designed by Jean Hultz in 1439. The original footings of the tower are of stone masonry on wooden piles. At the time of construction these piles were entirely submerged. About 1750 a new drainage system so lowered the level of the ground water that the tops of the piles were no longer submerged and they have subsequently decayed and permitted the tower to settle. Moreover the tower as finally completed was considerably higher and heavier than the one planned by Hultz at the time the footings were laid. In order to reinforce this old foundation and to replace the decayed piles, the columns of the tower have been encased in concrete to provide a hold for jacks and the whole tower has been jacked back into proper place and the old footings are being replaced by larger footings of reinforced concrete.

Status of Interstate Water Compacts

TREATY making between western states over irrigation water rights has been progressing rapidly since the Colorado River Compact was negotiated at Santa Fe, N. M., last November. Of the seven states involved in the Colorado case all but Arizona have ratified the action by legislative act. Compacts have been consummated or are under advisement in six other cases as follows:

The La Plata River compact between Colorado and New Mexico was negotiated at Santa Fe immediately following the Colorado River compact. Both states have ratified the treaty by legislative enactment. Congressional ratification is the final step. No enforcement of this compact will be attempted until Congress takes action. The La Plata River is a small tributary of the San Juan rising in the La Plata Mountains just southwest of Durango, Colo. The amount of water involved is small, about 60,000 acre-feet annually, but it is a concrete example of an interstate stream requiring legislative action by two states in order that future development may be placed on a sound basis. The commissioner for New Mexico was Stephen B. Davis, Jr., an attorney of Las Vegas, N. M.; Delph E. Carpenter represented Colorado.

Early in March an interstate water treaty was made between the states of Nebraska and Colorado on the South Platte River. R. H. Willis, engineer of Bridgeport, Neb., represented Nebraska and Delph E. Carpenter, Colorado. Nebraska has already ratified, but the Colorado legislature had adjourned at the time the compact was entered into and legislative enactment may be deferred until the regular session of the 1924-25 legislature.

Negotiations have been under way for over two years concerning an interstate settlement of the water of the Arkansas River. Litigation is in active progress on the Arkansas River concerning its interstate problem at this time. It has been pursued off and on for a period of over twenty years. George S. Knapp, Kansas state irrigation commissioner, and Delph E. Carpenter, for Colorado, constituted a commission instituted by the legislatures of both states to negotiate a compact.

Negotiations are now under way for an adjustment of the interstate water problems of the Rio Grande between New Mexico, Colorado and the federal government. Attorney J. O. Seth, of Santa Fe, is the New Mexico commissioner, and Delph E. Carpenter the Colorado commissioner. No commissioner has, as yet, been appointed for the United States. R. I. Meeker is associated as engineer for Colorado, with the attorney, on both the Arkansas and Rio Grande interstate water problems. He also served as engineer for Colorado on the Colorado and La Plata Rivers compacts.

An interstate water problem is imminent on the North Platte River among Nebraska, Wyoming, Colorado and the federal government. Wyoming, by legislative enactment in June, 1923, provided for negotiations, but so far a commissioner has not been appointed. Neither of the other states has passed legislation concerning this stream.

The states of New Mexico and Texas have provided by legislative enactment for a compact on the Pecos River between New Mexico and Texas. The federal government is also a party to the negotiations on account of the reclamation project in that stream basin.

Highway Development by the Alaska Road Commission

Wagon, Sled and Tram Roads—Trails, Ferries, Cableways—Truss and Suspension Bridges—Light Roads and Good Trails Needed—No Hard Surfacing—Day Labor—Organization and Transportation

By JAMES GORDON STEESE

Major, U. S. A. (retired); President, Alaska Road Commission, Juneau, Alaska

SINCE ITS organization in 1905, the Alaska Road Commission has expended about \$8,000,000 for the construction, repair and maintenance of roads, tramways, ferries, bridges and trails. The work thus far accomplished includes the construction of 1,114 miles of wagon road, 623 miles of sled road, 4,404 miles of permanent trail and 712 miles of temporary flagged trail, a total of 6,854 miles. For the current working season, about \$900,000 is available, including both federal and territorial funds.

The improvements contemplated for 1923 include a great variety of forms of pioneer construction, ranging

cessfully used during the past three winters and such traffic is expected to increase. Tractor freighting service is shown in Fig. 3.

"Trails" include any construction less than the above, suitable for dog sled or single-horse double-ender in winter or pack train in summer. Except when river surfaces are used (a practice which is very dangerous on account of numerous hot springs and overflows even in the dead of winter), some work is always necessary on account of the thick brush covering even the treeless regions, to permit the use of dog teams. "Flagged trails" represent cutoffs across frozen lakes, swamps and arms of the sea. The flags or tripods (see Fig. 1) are necessary on account of the absence of landmarks or to prevent travelers from getting lost in bad weather. Most of them must be replaced annually.

The commission maintains and operates about a dozen ferries, an 87-mile tram road with cars drawn by dogs, and several shorter trams. It has designed and erected twenty standard overhead cable trolleys varying in span up to 650 ft. Standard designs have been developed for all types of bridges. Structures built include many light cable suspension bridges designed for pack train and snow loads only, a steel highway span of 300 ft. for 20-ton trucks and combination spans up to 150 ft.

Hard-surfaced roads are not built, since neither the funds available nor the prospective traffic warrant such expensive construction. In the vicinity of the principal towns and mining districts, where the heaviest traffic exists, a heavier and wider surfacing is provided, about equivalent to a good macadam road in the eastern States. The great demand is for more and more mileage of light construction and the improvement of trails to road standard. The commission's program calls for an expenditure of \$10,000,000 as rapidly as the funds can be secured.

All important bridges are designed in and purchased by the head office. Wood and steel combination bridges are most common. Fir timber from the States is secured wherever practicable. Native timber is very inferior and unsuitable for bridge work, but must be used in many localities on account of excessive transportation charges. Hundreds of culverts of native wood are built every year, but more corrugated iron culverts are being imported and eventually few native timber boxes will be permitted. Standard plans are furnished superintendents and foremen in outlying districts and they then rustle their materials as best they can. Typical bridges are shown in Fig. 4, while Fig. 5 shows the driving of steel sheetpiling to form cylinder piers which are filled with concrete.

Construction Methods and Outfits—Since Alaska is a mountainous country much heavy rock work is encountered. The commission owns several portable compressor outfits, each capable of operating several air tools. The Keystone Canyon relocation of the Richardson Highway involved three miles of benching on the vertical rock walls of the canyon some 300 ft. above

FIG. 1—TYPICAL ALASKA HIGHWAYS

Above: view on Ophir-Tokotna Road. Below: winter trail; the tripod is a marker set up by the road commission to indicate the route.

from a cableway and cage over a glacial torrent, or a line of stakes set across the treeless tundra or a frozen arm of the sea, to a well located, graded and graveled road, or a steel bridge of five 150-ft. spans on piers consisting of twin cylinders of interlocking steel sheetpiles filled with concrete. A typical road and winter trail are shown in Fig. 1, the tripod on the latter being a marker to indicate the route. A road map is shown in Fig. 2.

Types of Construction—Under the classification of the commission, "wagon roads" are any roads cleared, grubbed, ditched, graded and drained sufficiently to accommodate wagon traffic. Light motor vehicles (up to 2-ton trucks) are now using these roads in increasing numbers and about 800 miles have been given a gravel surface 14 ft. wide at an increased first cost, but with an eventual saving in annual maintenance charges. "Sled roads" are cleared and graded like wagon roads, but not grubbed. They are drained only sufficiently to prevent their destruction by the summer rains. Their wearing surface is of snow. Double bob-sleds, drawn by two, four or more horses, haul heavy loads over these roads as well as over the wagon roads in winter time. Caterpillar tractors were suc-

FIG. 2—PRINCIPAL ROADS AND TRAILS OF ALASKA

the bed of the river, with two highway suspension bridges of 150- and 175-ft. span across side canyons.

Clearing and grubbing is let by contract wherever practicable. Dense timber is found over a large part of the Territory. Grading is done with grading machines drawn by 5-ton crawler tractors. For the graveling, steam shovels load dump trucks or 3-yd. dump trailers drawn by 5-ton crawler tractors. In most cases, the crews are working far from a base of supplies, and must be housed and fed. The commission owns a number of horses and has warehouses, caches, garages and barns located at suitable points. Its road equipment has a value of about \$500,000.

Due to the remoteness and inaccessibility of most of its projects, the commission performs most of its work by day labor. The pioneer nature of much of this work also precludes the preparation of specifications in advance at any relatively reasonable cost for surveying, engineering and supervision.

The work varies from primitive pioneer cruising and blazing of pack trails to surveying and locating well graded gravel roads and involves the constant improvement of old roads or trails. The condition of the roads continues to improve by thawing and drying out from year to year. For this reason, the carrying on of construction through protracted periods has not always been a disadvantage. The cruising, location and clearing of the right-of-way and the gradual grading results in a road structure at less total cost than would have been possible had the construction been completed the first season. In fact, the construction of a road in one season is impossible in the large areas of marshy and permanently frozen ground which always require two or three seasons of exposure to the sun's rays to become dried out and compacted. A great deal of pioneer reconnaissance work is performed each year in developing new districts.

Perhaps the worst obstacles to road construction are the numerous glacial streams which cannot be avoided and cannot be permanently controlled at any reasonable cost. Their vagaries are inconceivable. Just out of Valdez, the Richardson Highway crosses the delta of Valdez Glacier for $3\frac{1}{2}$ miles, in which distance there are

twenty-six trestles or short-span bridges aggregating nearly 2,000 ft. in length. During different seasons of different years water flows under any, all or none of these bridges, and nearly every year new openings are broken out between bridges. A pile driver is maintained constantly on the job.

On smaller streams, bridge abutments may be placed on permanent banks upon which heavy trees are growing, only to disappear a year or two later. Long truss spans have been left high and dry, the river moving half a mile or more to a new location, and a year or two later it may move back. In some cases wing dams, dikes and revetments have been successful for a few years, but sooner or later they all go out.

Supply and Transportation—The question of supply is the most difficult feature of engineering construction work in Alaska. Most of the interior can be reached only by river boat during the short summer season or by dog team in winter. A rate of 25c. per pound is not uncommon, and the community that can land its supplies from the nearest base for 10c. per pound is considered lucky.

FIG. 3—TRACTOR HAULING IN ALASKA

Above: hauling poles for corduroy road in Seward Peninsula. Below: tractor-trailer freight train on Richardson Road, leaving Chitina for Fairbanks.

In the fall of 1920, the commission ordered two 90-ft. combination truss spans for a river crossing on the Richardson Highway, twenty-eight miles from Fairbanks. This material left Seattle during the following summer and was lightered ashore at St. Michael in time to catch the last boat up the Yukon River. After making nearly a thousand miles, this boat was frozen in for the winter about 200 miles short of destination. The lowest bid for freighting over the snow was \$135 per thousand feet b.m., a not unreasonable charge for the service, but too expensive for our resources. The material reached Fairbanks on the first boat in June, 1922, and was freighted out by truck the twenty-eight miles at a cost of 50c. per ton-mile. Meanwhile, the old bridge was patched up at a cost of some \$1,200 to last out the 1921 season.

About this time the Alaska Railroad was completed and as a result the transportation situation in the Tanana valley has been radically changed. Last spring,

FIG. 4—TYPICAL HIGHWAY BRIDGES IN ALASKA

Above: suspension bridge over Nome River, and truss bridge over Snake River at Nome. Below: trestle near Miller's on Richardson Road, and timber truss bridge over Moose Creek.

in less than 90 days the commission took down a 100-ft. and 150-ft. combination span, using the ice as falsework, freighted them three miles with horse sleds, then shipped them 265 miles over the Alaska R.R. standard gage and 90 miles over the narrow gage, then freighted them twelve miles by tractor-drawn sleds and re-erected them over a river on the other side of the Alaskan Range with ice as falsework.

Richardson Highway—The most important project of

construction found anywhere in the Territory. The south coast has heavy rainfall and snowfall and is heavily wooded. The interior valleys are comparatively dry, have light snowfall and a very low temperature. The ground is permanently frozen immediately under the moss. The passes lie well above timber line and near the permanent snow line. Throughout is a jumbled mass of steep snow-clad mountains, glaciers, canyons, rivers, swamps and bare wind-swept wastes.

Organization—The Alaska Road Commission is composed, in addition to the writer, of John C. Gotwals, chief engineer, and P. A. Agnew, secretary and disbursing officer. Its headquarters are at Juneau, the capital of the Territory. District offices, each under a superintendent, are maintained at Eagle, Chitina, Valdez, Anchorage, Fairbanks, Nenana, Tokotna and Nome. A purchasing office is maintained at Seattle and a sub-office at Washington, D. C., during the Congressional hearings. The extent of the Territory may be realized from the fact that it would take a single individual, if he traveled continuously by the best means of transportation procurable, two years to inspect all the work for which the commission is responsible.

FIG. 5—BUILDING PIERS FOR NIZINA RIVER BRIDGE
Steel sheetpiling driven to form cylinders which are filled with concrete.

the commission is the Richardson Highway, extending from Valdez, an open-all-the-year south coast port, via Fairbanks to Circle, on the Upper Yukon River, a distance of 521 miles. It crosses the Chugach or Coast Range through Thompson Pass at an elevation of 2,750 ft., the main Rocky Mountains or Alaskan Range through Isabelle Pass at 3,300 ft., and the portage between the Tanana and upper Yukon River valleys. The 371-mile section between Valdez and Fairbanks has been passable for light automobiles since 1913; about fifty miles have been completed on each end of the 160-mile extension to Circle, leaving a gap in the middle of about sixty miles still under construction, but used as a bob-sled road in winter time. Along this highway are met about all the problems of road

New England Railway Consolidation

Consolidation of the railways of New England into a group or regional system is recommended in the report of a committee appointed by the governors of the six New England states. The other alternative in the general project of railway consolidation was the partition of these lines to form New England extensions of outside groups or trunk lines, as noted in *Engineering News-Record* of July 26, p. 127. The proposed plan includes the Boston & Maine R.R., 2,515 miles; the New York, New Haven & Hartford, 1,950; Maine Central, 1,201; Bangor & Aroostock, 626; Rutland R.R., 415; Central New England, 295, and the New York, Ontario & Western R.R., 568 miles, making a total of 7,570 miles. It excludes the Boston & Albany (as part of the New York Central System), the Central Vermont and Portland lines of the Canadian National Railways, and all lines of the Canadian Pacific Railway.

Monorail Railroad Constructed to Tap Desert Mine

Fordson Tractor Hauls Heavy Loads on Grades of 10 Per Cent and 40-Deg. Curves, on Line to Cost Only \$5,000 to \$7,000 per Mile

A MAGNESIUM sulphate deposit owned by the American Magnesium Co. and located near the Death Valley Desert in southern California is to be tapped by a 28-mile monorail railroad extending over the Slate Range to the Panamint Range. Of this line about 16 miles has been completed and is carrying construction trains which are delivering material for continuing the railroad. Although detailed costs are not available, the type of construction selected, which was chosen because of the fact that it would require very little grading and would permit of sharp curves, is estimated to cost about \$7,000 per mile in the rough

TYPICAL CONSTRUCTION IN THE MOUNTAIN COUNTRY
In the absence of rainfall streams are unknown and canyon bottoms make good roadbeds.

mountainous country and about \$5,000 per mile in the desert with no rock work or sharp curves involved.

The construction consists of standard 6x8-in. ties, 8 ft. long, placed on 8-ft. centers. Each bent consists of a single plumb-post placed in the center of the tie and braced on either side. The plumb posts carry a 6x8-in. stringer which in turn supports the single 50-lb. rail. There are also two side rails of timber, carried by the braces, which act as guide rails, their vertical faces making contact with the rollers on either side.

The engine and cars are designed like a pack saddle, and are suspended on two wheels from the single rail. Equilibrium is maintained by the rollers on either side which contact with the timber guide rails. The motive power at present being used is Fordson tractors chain driven from both the front and back wheels which are 24 in. in diameter. On tests made with this equipment an engine so constructed carried a 5-ton load on grades up to 10 per cent. Loads of 3 tons were able to make a 14-per cent grade. This seemed to be about the maximum load that could be successfully handled on such steep grades with the Fordson power unit.

The maximum grade on the railroad as built is 10 per cent with 40-deg. curves. In operating under these

MONORAIL TRAIN HAULING CONSTRUCTION MATERIAL

conditions the only trouble so far experienced was in twisting drive shafts. This difficulty was eliminated by substituting a chain drive. Under present conditions one locomotive ordinarily hauls two cars carrying a total of 5 tons of timber distributed on all three units. The cars are 14 ft. long with wheelbase 10½ ft. long. Equipment now used has rigid wheelbase construction, but patents have been taken out on swivel cars which will greatly reduce resistance on the curves.

The foregoing was prepared from information supplied by T. H. Wright of the T. H. Wright Mercantile Co., Los Angeles, who is building the monorail line.

Elimination of Cat-Tails from Reservoirs

A COLORADO correspondent recently requested information as to the eradication of cat-tails. Lyman E. Bishop, consulting engineer, Denver, who has earned the title of cat-tail expert because of his contentions as to their existence only under swamp conditions, in an investigation in a law-suit over seepage and ground water levels, suggests lowering the ground water level below the creeping root stalks. If the ground is dry for any considerable time the plant dies.

C. R. Knowles, superintendent of water service, Illinois Central R.R. Co., makes the following comment:

We have had some experience in removing water hyacinths and water lilies from our reservoirs in the South. We have also had some experience in removing cat-tails in our northern reservoirs. Our practice has been to pull them out by hand, destroying the roots as far as possible, but I do not know of any method whereby they can be completely removed. The use of creosote oil will help considerably and if used diligently it will in time eradicate cat-tails or other aquatic growth. The objection to creosote oil, unless used carefully, is its effect on the water. The proper method is to apply the oil at the water's edge. As the oil is heavier than the water, it will sink and come into contact with the roots of the plant, which it will kill.

It is suggested that the creosote be tried experimentally at first. If possible to do so a temporary breakwater should be placed between the growth of plants and the main portion of the reservoir. This practice was followed at one of our reservoirs in Mississippi with good success in the extermination of water lilies. It is best to use the creosote when the stage of water is at the lowest as often the plant life may then be killed without affecting the water.

In a recent issue *Nature Magazine* notes many uses of cat-tails. The Germans during the war made an excellent bread from the pollen. A cotton substitute is made from the brown spikes and an artificial silk from cat-tail floss. The roots are fairly rich in starch and sugar and the Iroquois Indians formerly dried and pulverized the roots yielding a sweet-tasting flour (30 per cent starch and sugar) from which bread and puddings were made. In swampy lands from 2 to 4 tons of flour per acre may be secured. Our Colorado correspondent may find it more profitable to cultivate than to eradicate his cat-tails.

Underpinning New York Public Library Without Shores

Used Method Known as "Stealing"—Rammed Mortar Transfers Load to New Footings—Unusual Rock Conditions

By C. S. RINDSFOOS

Jarrett-Chambers Co., Inc., New York City

THE UNDERPINNING of the north wall of the New York Public Library is of interest not only because the structure is a monumental one but also because of the method used and the character of the material encountered. The necessity for this work was occasioned by the extension of the Queensboro Subway from its present terminus near Park Ave. to a new terminus at Eighth Ave. This extension will have its south wall along the building line of the north face of the library, and since the bottom of the cut for the subway had to be made at a considerable depth below the footings of the building, it was necessary to underpin these footings before the cut was made.

The old spread footings of the building were of concrete and rested on hardpan. The records from the first subway constructed in 42nd St. indicated that rock was from 3 to 10 ft. below the underside of these footings. This rock, however, was found to be of a decomposed nature for a depth of as much as 13 ft., and much softer than the hardpan. It was therefore essential to carry the underpinning through this soft rock.

In view of the monumental character of the structure involved, and because the underpinning would not only have to sustain the weight of the building but also act as a retaining wall to support the earth behind it, and finally because this underpinning would be subject to unusual shock from the blasting in the rock cut alongside and below it, more than usual precautions were taken in the design and actual construction.

After a steam shovel had made the first cut down to a level of about 2 ft. above the underside of the old footings, the work of underpinning began. Holes 4 ft. wide and about 30 ft. c. to c. were sunk along the side of the building and carried down through the hardpan and soft rock to solid rock. These holes were drifted back under the old footings to a distance of 6 ft. and then concreted up to within 6 in. of the underside of the old footings. After this concrete had set sufficiently the 6-in. space was rammed full of a 1:2 mortar mixed just wet enough to be molded into balls. These balls were thrown into place by hand and rammed home with a sledge hammer and a thick wooden block. V-shaped

FIG. 1—COMPLETED UNDERPINNING FOR NORTH WALL OF NEW YORK LIBRARY

The old spread footing can be seen on the right just below the trusses supporting the sidewalk.

recesses were cast in the side of these piers to make a bond with the subsequent work. In similar manner a second and a third set of concrete piers was built. When these piers were completed the intervening spaces were excavated to solid rock and closed with a curtain wall 3 ft. thick.

It should be noted that this work was carried on without the use of any shoring whatsoever. The process used is sometimes known as "stealing" and while not unusual for small buildings, has, so far as the writer knows, never before been employed so extensively or for such an important structure.

The use of rammed dry mortar in preference to the ordinary custom of using granite blocks and steel wedges was found to be most effective. Not the slightest settlement of the building occurred. Before approving of this method the engineers tested samples of mortar mixed as specified for the 6-in. layer of rammed mortar and found that it sustained a load of over 4,000 lb. per square inch.

The decomposed rock encountered on this job raises some interesting questions. It is no new thing to find a layer of soft rock overlying the solid rock on Manhattan Island, but rarely of anything like the thickness here described, which was as much as 13 ft. deep in places. One wonders whether this process of decomposition occurred before or after the overburden was laid down in past geological times, and, if after, at what rate does it go on. It might be inferred that, had the rock disintegrated before it was covered with

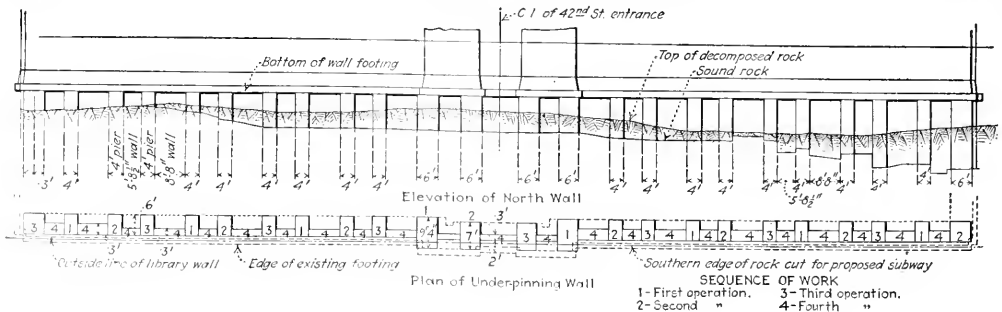

FIG. 2—PLAN AND ELEVATION OF THE NORTH WALL

overburden, the rainwater would have washed it away as fast as it weathered. This consideration, together with the fact that, when exposed to view, it has all the appearance of sound rock, leads the writer to believe that the rock has softened in place and that this change is still going on. What, then, will be the effect on some of the heavy, deep foundations in other parts of the city? If this softening is going on now, what will be the effect of the process in the case of those buildings which have lately been founded on steel pipes loaded up to 90 tons per pipe, to say nothing of foundations constructed by more positive methods.

The underpinning of the library building was performed by Jarrett-Chambers Co., Inc., New York City, under the general supervision of John H. Meyers, engineer, 2nd Division, Transit Commission, and Carrere & Hastings, Shreve, Lamb & Blake, architects for the library.

Concrete Block Ties on Railways in India

CONCRETE ties of the Stent design, of which about 200,000 are in use on over a hundred miles of main track in India, are of the block type, each tie consisting of a pair of reinforced-concrete blocks connected by a steel tie-bar. Fig. 1 shows these ties on the broad gage (5 ft. 6 in.) line of the Southern Punjab Ry., near Delhi, and their construction is shown in Fig. 2. The dimensions vary according to the gage and character of track and for maximum axle loads ranging from 14 to 26 tons. Where double-head rails are used, cast-iron chairs are attached to the blocks.

In the design shown by Fig. 2, for a gage of 5 ft. 6 in., 110-lb. rails and 26 tons axle loads, the blocks are 25x16½ in. on the base and 6½ in. thick, reinforced by upper and lower sets of horizontal bars connected by stirrups. Secured to this reinforcement is an anchor

FIG. 3—DETAILS OF A TYPICAL PIER

whose end projects from the block and to which the steel tie-bar of I-section is attached by a split pin. Four plugs of treated wood inserted in the block serve to hold either drive spikes or screw spikes. The upper surface has an inclination of 1 in 20 to give the rails the desired inward slope. Each block weighs 166 lb. and the tie-bar 16 lb., the total weight of tie with all fittings being about 350 lb. A concrete mix of 1:2:3½ is made with 2 parts hard silica quartzite and 3½ parts of ½- to ¾-in. aggregate. Only sufficient water is used to make the concrete flow when the form is shaken on a vibrating table. After being left in the forms for twelve hours the ties are cured thirty days under water and then thirty days in air, but are usually at least three months old before being laid. Their life is estimated at fifty years.

A few of the ties which have been in service for about nine years are said to be in as good condition as when laid, certain defects in earlier experimental ties having been eliminated. Their first cost in India is higher than that of wood ties, as steel and cement have

FIG. 1—CONCRETE BLOCK TIES ON SOUTHERN PUNJAB RY.

to be imported, but when compared on the basis of life and cost the concrete ties are said to show a marked economy. These ties are in use on several railways in India, their most extensive use being on the Northwestern Ry., which has laid them on seventy-five miles of track and is laying fifty miles additional this year. Broken stone ballast is used, 6 to 8 in. deep under the blocks.

These concrete ties are the invention of D. H. Stent, consulting engineer, Delhi, India (or care of Grindlay & Co., London, England), who was formerly executive engineer of the Bombay, Baroda & Central India Ry. They are manufactured by Bird & Co., Calcutta, India.

Signs Removed from Washington Highways

Advertising signs have been gradually eliminated from Washington state highways, according to a report from the highway division of the Department of Public Works in that state, and in a final "clean-up" in the Spokane district 5,000 advertising signs were removed from 1,100 miles of state roads. Although advertisers have offered some objection, the traveling public is very much pleased, according to the report, which states that "the highways look much cleaner and in many cases are safer, as signs on curves have been eliminated as much as possible."

FIG. 2—THE STENT CONCRETE TIE

Utilization of Methane Gas from Imhoff Tanks

One Year's Experience at an Essen-Rellinghausen Plant Indicates Gas Production of 0.3 Cu.Ft. per Capita Daily Which May Be Used for Various Purposes

BY DR. ING. KARL IMHOFF

Chief Engineer of the Ruhrverband, Essen, Germany

Translated from the German by HAROLD M. LEWIS of the
Physical Survey, Plan of New York and Its Environs

SINCE the time when sludge chambers were first used in sewage disposal it has been known that the gases developed in them were useful ones. These gases come from the biological destruction of the sludge (not from the liquid sewage, as has recently been emphasized in published articles). Their usefulness consists chiefly in the high content of methane (fire damp, marsh-gas), CH_4 .

Collection of the Gas—The gases have not been much utilized up to the present time because it has been considered necessary to build large roofs above the water level to collect them. This not only required heavy expense but also greatly complicated the operation of

lead obliquely to the vents at the water level—the gas bubbles arising from the entire surface of the sludge. (See following articles by me: "Eight Years of Imhoff Tank Design and Operation," *Engineering News*, Jan. 6 and 13, 1916, pp. 14 and 52; "Separate Sludge Digestion and Improved Mixing in Imhoff Tank," *Engineering Record*, July 22, 1916, p. 101, reprinted in *London Surveyor*, 1916, p. 187.) Imhoff tanks thereby permit a simple type of gas-collecting installation by making small changes in the vent shafts. As a result of this opportunity there has recently been constructed in the Ruhr coal district the first large municipal sewage-works with provision for collecting all of the gas produced.

FIG. 1—IMHOFF TANKS PIPED FOR COLLECTING GAS

The first large municipal plant in the Ruhr coal district, Germany, with provision for collecting all the gas produced.

the plant. The few examples of the utilization of the gases which have been mentioned in the technical press deal with small sludge chambers which already had, for other reasons, a solid concrete roof. It is not recommended that large plants should be built of this type, where the gas roof is above the water level and there is therefore a large gas chamber, for if there is the least leak in the roof a great loss of gas will result. Still worse, there is the danger of an explosion from the entrance of air, and many accidents of this kind have already been recorded.

It is much better to place the gas-intercepting roof below the water level. In the two-story Imhoff tanks, with separate settling and sludge digestion chambers, this type of construction is very suitable, for they already have, as partitions between the two chambers, thin sloping reinforced-concrete walls which collect and

Figs. 1 to 7 show one of these plants (Essen-Rellinghausen of the Ruhr association) from which all the gas produced during the several months of its operation has been conducted to the city gas plant.

The new type of vent chamber, as reconstructed, is shown in the cuts. About 3 ft. below the water level there is constructed a nearly horizontal concrete roof which has an opening in it about 3 x 2 ft. in size. Over the opening a funnel-shaped gas hood is placed, the bottom edge of it projecting about 1 ft. below the surface of the water. To keep the coarse parts of the scum away from the gas collector a sloping fine screen is used which can be reached through an opening for cleaning. The screen is necessarily made of wood or a resisting metal, as iron bars would be quickly destroyed. The scum collecting under the screen can be removed through the opening at the side without interfering with the

FIG. 2—DETAILS OF GAS HOODS AND PIPING

Concrete roof and water-sealed hood built in gas vent, with inclined screen to exclude scum from hood. Top of each hood connected to piping system.

collection of the gas. From the upper end of the hood small iron pipes lead the gas to the place where it is to be used. From time to time the particles of scum which have collected under the hood must be removed. For this reason the gas hood is made removable (Fig. 6). While the hood is turned back the piping is kept closed by means of a stop cock near the top of the hood. When the hood is again replaced a blowoff valve on the top of it is opened for a short time to let any air escape which may have gotten underneath it. As soon as all the air is forced out of the hood the blowoff valve is closed and the stop cock in the pipe line is opened again. In this way even a small amount of air is absolutely prevented from getting into the piping. The depth of the hood noted above, 1 ft. below the water level, is, in the present case, sufficient to overcome the gas pressure necessary to force the gas into the city gas system. In every case this depth must be computed.

If the gas piping is shut off, or if a pipe becomes blocked for any reason whatever, the pressure under the gas hood will become greater and the gas will pass under its edge into the open. The gas hood therefore works exactly like a safety valve.

Fig. 7 shows the secondary sludge digestion tank which, in the Essen-Rellinghausen plant, as in most of the newer Imhoff tank plants, is located near the sludge drying bed. Its purpose is to restore to the sludge the gas content which has been lost by pumping, so that it will dry more readily on the drying beds. A gas roof is placed over the entire surface of this tank. In the middle of the roof is an opening for the gas and at the outer edge is a small circle of slots through which the sludge can pass as the surface of the sludge is lowered.

Amount of Gas—In a year's time a quantity of gas equal to 0.3 cu.ft. per capita per day can be assumed. A city of 100,000 inhabitants can therefore figure on 11,000,000 cu.ft. of combustible gas per year. In summer the quantity of gas is greater than in winter. It also increases if for any incidental reason the amount of sludge brought to the tank increases. If no fresh sludge is added to a tank the production of gas stops for fourteen days.

Composition of the Gas—In general the mixed gas which results consists of the following components in percentages: Methane (CH_4), 65-90; Carbon dioxide (CO_2), 5-35; Hydrogen (H), 0-10; Nitrogen (N), 0-8.

In a well ripened Imhoff tank one can usually figure on the following percentage combination; Methane (CH_4), 80; Carbon dioxide (CO_2), 20; Hydrogen (H), 0; Nitrogen (N), 0 to 8.

The most important thing is the proportion between the methane and the carbon dioxide, as the latter greatly decreases the value of the gas mixture. Apparently this proportion depends principally upon the water. That is readily explained as the two gases act very differently with water; methane dissolves in it only with difficulty, but carbon dioxide is readily soluble. The carbon dioxide is taken up by the sludge chamber water almost to saturation and only the excess over this amount appears as carbon dioxide in the mixed gas

FIGS. 3 TO 6—VIEWS SHOWING ARRANGEMENT AND OPERATION OF GAS HOODS, SCREENS AND PIPING

3. Gas opening with sloping bar screen. In foreground, side opening for scum.

6. Gas hood turned back for cleaning.

escaping from the sludge chamber. If the sludge chamber water is restored with fresh water it again has the power to absorb large quantities of carbon dioxide and little of this appears in the escaping gas. This clearly explains why the content of carbon dioxide in the mixed gas in separate sludge digestion tanks is much higher (up to 35 per cent) than in Imhoff tanks, where the sludge water has the chance to equalize itself, through the sludge slots, with the water in the settling compartment. Also it is readily understood that shortly after drawing off sludge from an Imhoff tank (during which process a quantity of water corresponding to the amount of sludge drawn off is forced into the sludge chamber) little carbon dioxide is, for some time, to be found in the mixed gas.

The *hydrogen* content of the mixed gas is particularly interesting. Hydrogen is most generally not found in good Imhoff tanks. On the other hand it is known that fresh faeces decompose first into an acid fermentation which develops only hydrogen and carbon dioxide, but no methane. In accordance with this, hydrogen is found in large quantities in the first stages of operation of Imhoff tanks. Likewise hydrogen can appear later when there are disturbances in the operation.

The reasons for the presence of *nitrogen* in the mixed gas have not yet been clearly explained. The nitrogen has no bearing on the utilization of the gas.

The *heat value* of the mixed gas is generally 7,000 to 9,000 calories and varies principally and inversely with the content of carbon dioxide. The high heat value is explained by the methane. In this respect the gas is superior to the city gas, for the gas of the city of Essen, for example, has only 4,200 calories, which are principally due to hydrogen.

Cleaning—As the sludge chambers are fairly warm water separates out from the gas in the cold pipe lines. It is therefore necessary to provide the pipes with drip-pots.

As a rule *hydrogen sulphide* is not found in the mixed gas and is undesirable as it corrodes the pipes and gas meters. As an exception, this gas may appear in those plants which have to receive very foul sewage from cesspools. It is then advisable to construct in the pipe line a filter of bog-ore such as is also found useful in municipal gas plants for the retention of hydrogen sulphide.

The content of *carbon dioxide* is, for many purposes, such as the delivery of the gas at the municipal gas plant, unarmful. If it is ever for any reason necessary to free the gas of carbon dioxide it can very easily be done by making use of its previously mentioned easy solubility in water. For example, the mixed gas might be pumped through certain sludge chambers where the sludge water has been frequently renewed. If the gas is to be delivered under pressure the necessary high pressure can be utilized for the elimination of the carbon dioxide. It is then only necessary to insert several bottles filled with wash-water between the compressor and the tanks for the receipt of the gas; the carbon dioxide must be removed from these bottles from time to time. Such a plant has been in operation in Essen for over a year.

A surprisingly simple method of freeing the mixed gas of *hydrogen* has developed from the observation already referred to above—that hydrogen arises only in the decomposition of fresh faces, but not in a well-seasoned Imhoff tank. It must nevertheless be admitted that, with the fresh sewage, there are always received new particles of sludge which are already more or less in acid fermentation and therefore contain hydrogen. The fact that none of this hydrogen generally appears above the surface of the water forces one to the conclusion that biological forces must be at work in Imhoff tanks to convert the hydrogen into methane. To verify this by a practical experiment an artificially prepared gas mixture, to which 20 per cent of hydrogen had been added, was blown into the bottom of a well functioning Imhoff tank. The experiment succeeded fully, for no trace of hydrogen was found in the gas mixture coming from the tank, but only methane and carbon dioxide. It must be accepted that the bacteria of ripe sludge convert the hydrogen, in the presence of carbon dioxide, into methane and water in accordance with the following formula: $4\text{H}_2 + \text{CO}_2 = \text{CH}_4 + 2\text{H}_2\text{O}$. Thereby it is possible to obtain a mixed gas entirely free from hydrogen if the gas, just as soon as it comes from tanks

which have not yet been ripened or where the operation may for some other reason be disturbed, is blown again through ripe sludge.

By the use of the methods outlined above for the removal of the carbon dioxide and hydrogen from the mixed gas it is possible, according to our experience, to be assured of obtaining continually a cleaned gas which contains 92 to 98 per cent methane, 0 to 8 per cent hydrogen and perhaps some carbon dioxide.

Use of the Gas—The most natural use is for the needs of the disposal plant itself, for heating and the generation of power. For instance, in several plants of the Ruhr association the chlorine disinfection houses are heated with sludge gas. If the municipal gas works, or at least a city street main, is near and accessible it is planned to deliver the gas to the gas works. Where neither of these methods of utilization is possible it is practicable to compress the gas in drums under about 150 atmospheres pressure and to sell it in this way for burning. This gas is, for example, very useful for welding and cutting, particularly as it is free from hydrogen.

For certain purposes it is desired that the gas shall not only be free of hydrogen but also of carbon dioxide. This is especially important in its applications in the chemical industry, where methane has recently been very much wanted for many purposes.

Cost—The construction cost for the entire gas collecting apparatus, including the piping on the disposal plant grounds, amounts to only 1 per cent of the cost of constructing the Imhoff tank plant. In those cases in the Ruhr coal district where the gas is delivered to the municipal gas plant the price paid by the city amounts to two-thirds of the cost of the regular municipal gas. In spite of this low price the receipts cover half of the total operation costs of the Imhoff tanks. As the price paid by the city is still much too low in comparison with the calorific content, it is assumed that the price can later be raised so that the entire operation cost will be covered. Based upon the dealings which have up to this time been carried on with chemical works, it is expected that, with the delivery of the gas for special scientific purposes, a still higher return can be received.

In any case present experience justifies a recommendation that all Imhoff tank plants be equipped with gas collecting apparatus. This is warranted not only when there is need for the gas at the plant itself but also if the gas can be delivered to the municipal mains or if it is possible to make an agreement with a chemical works. On the other hand every municipal gas plant should consider the question whether it is possible to obtain from the municipal sewage-works gas to augment and improve that in their mains. Also many chemical plants will find it advantageous to seek a connection with a large sewage-works which can furnish them with a continual and inexhaustible supply of the valuable methane.

Railway Electrification in Central Africa

The conditions under which the Leopoldville-Metadi R.R. will be electrified have been announced by a statement from the Belgian Minister of Colonies, which has been received by the Department of Commerce. The company has available 30,000 hp. for the first electrification work and can obtain 100,000 hp. more. The electrification will cost 150,000,000 francs. The gage of the line will be changed from 0.75 to 1.06 meters.

Problems and Progress in the Field of Water Supply

High Points in the Papers and Discussions of the Annual Convention of the New England Water Works Association

AT THE forty-second annual meeting of the New England Water Works Association at Burlington, Vt., Sept. 18 to 21, some fifteen papers and lantern slide talks were presented. In addition to these were a few topical discussions on Superintendents' Evening. Some of the high points in the technical proceedings are given below. The business proceedings and the presidential address—the latter dealing with society affairs—are outlined in the news section of this issue.

Filtration of Burlington's Water—Appropriately, the first paper to be presented dealt with the water supply of Burlington, Vt., the city in which the convention was held, and the second one with Vermont water supplies. Oliver J. Channing, pumping engineer, and in charge of the Burlington filters, outlined the benefits of filtration and chlorination at Burlington.

Notwithstanding a two-mile extension of the waterworks intake into Lake Champlain, Burlington continued to have much typhoid. In the period of 1904-08, there were 151 cases. Mechanical filters were put in operation on April 15, 1908. For the two years 1909-10 there were 29 cases of typhoid. In December, 1910, the use of hypochlorite was begun. The following year the typhoid cases were seven, of which six were classed as contracted out of town. In 1921, liquid chlorine was substituted for hypochlorite. In 1922 there was only one case of typhoid in Burlington.

In the discussion of Mr. Channing's paper, M. N. Baker, associate editor, *Engineering News-Record*, said that when he entered the University of Vermont, in 1882, the members of his class were warned by the president to drink sparingly of the city water until their systems became accustomed to it, lest intestinal disturbances be caused.

Public Water Supplies of Vermont—Most of the water supplies of Vermont are from surface sources, according to a paper by Charles P. Moat, chemist, Vermont State Board of Health, Burlington. The only filtered supplies are those of Burlington and St. Johnsbury. At the latter place slow sand filters were installed many years ago. Only a few supplies are chlorinated but more of the surface supplies might well be. High B. Coli counts in one of the Vermont supplies were apparently traced to droppings from deer in the drainage area. The Burlington filtered supply rarely shows taste or odor although the service reservoirs are uncovered. However, much of the supply goes to consumers, direct, and the stored water is frequently freshened, as the pumps deliver through the distribution system to the reservoir.

Sub-Surface Supply, Newton, Mass.—A paper sent by Edwin H. Rogers, city engineer, Newton, Mass., brought out the fact that after many years of use the driven-well supply of Newton had not deteriorated in quality nor given trouble from iron. This was attributed to the moderate draft upon the wells.

Reservoir Covering—A lengthy paper on "Covering Open Service Reservoirs, in Which Filtered or Ground Waters Are Stored" was sent by George C. Bunker and

August G. Nolte, in charge and assistant engineer in charge of water purification, Panama Canal, Ancon, C. Z., and was read in abstract by R. S. Watson. The main point of the paper was not only that such reservoirs should be covered but also that covering them as a part of the original construction will reduce first cost. Where covers have not been provided they should be added. Experiences with open and covered reservoirs in the canal zone, showing the benefits of covers, were cited. Attention was called to the fact that at St. Louis, Mo., E. E. Wall, water commissioner, has in seven successive annual reports, advised covering the Baden and Bissell's Point reservoirs, with repeated failures to get the necessary money from the city authorities.

C. W. Sherman, of Boston, after referring to reports that the Boston Metropolitan Commission is planning to filter the Sudbury and Cochituate supplies, raised a question as to what would happen to the water thus filtered during storage in uncovered reservoirs. He thought that the present Chestnut Hill reservoir and Spot Pond are already polluted by sea-gull droppings.

Some Additions to New England Water-Works Plant—A paper by Allen Hazen, New York City, on "Some Additions to New England Water-Works Plants" was read by one of his associates, H. M. Pirnie. At New Britain, Conn., some impounding reservoirs have been built to utilize the entire economical surface yield of the drainage area and wells and pumps have been installed from which water is being pumped to a reservoir with capacity in excess of its tributary yield. At Springfield, Mass., which has had a more rapid and continuous growth than any other city in New England, and which supplies water to other municipalities, the capacity of the slow sand filters is being doubled. Studies are being made for the filtration of the new gravity supply, now under construction, for Providence, R. I. Tests show more color in the water than was expected. Because of this and of site conditions unfavorable to the large area required for slow sand filters, mechanical filtration is considered better for Providence. To avoid red water troubles, a large coagulation basin, well baffled, is proposed. Aeration both before and after filtration is also proposed, both to remove taste and odor and to reduce carbonic acid so as to get a "quieter water." Near the New England territory are Poughkeepsie and Albany, N. Y., both of which are using Hudson River water. These supplies are badly polluted and must ultimately be abandoned. It seems advisable to continue their use for some years longer, and to continue to make the river water safe by the present method of double filtration—scrubbers or rapid filtration prior to slow sand filtration. With pre-filtration, the slow sand filters can be used for long periods without being cleaned. The Albany plant is now being overhauled, particularly the prefilters, which had been "demoralized" and become badly clogged.

Care of Large Watersheds—A general review of the forestry work, sanitary control and other matters per-

taining to the surface water supplies of the Boston Metropolitan District was given by Frederic I. Winslow, an engineer of the district located at South Framingham.

Rapid Sand Filtration at Cambridge, Mass.—The first mechanical filters for improving the sanitary quality of water, said Col. George A. Johnson in a paper on the Cambridge filters, were put in operation on April 14 of this year. The plant has a capacity of 14 m.g.d. In the main it follows standard practice. A feature that is uncommon but not new is the return of the washwater to the sedimentation basin. The water is chlorinated after filtration. The construction details of the plant were described in a supplementary paper by Mr. Stevens who was in charge of construction for Colonel Johnson. A paper describing the Smolski system of reinforcement for the concrete roof was sent by Mr. Smolski.

In the discussion of the main paper, W. C. Hawley, Wilkensburg, Pa., said that in his filters, built in 1909-10, the washwater is also returned to the sedimentation reservoir, but not until after detention in a separate settling basin. The net washwater at Wilkensburg is only 0.1 per cent of the amount filtered. Frank A. Marston, Boston, commended the use of the Venturi meter for washwater control, used at Cambridge, as a means of guarding against the wrecking of the filter underdrainage system. As to the Smolski roof being cheaper than the groined arch, as indicated in the papers on the Cambridge filters, Mr. Marston said that relative costs varied with local conditions, including the experience of contractors bidding on a job. In one case Metcalf & Eddy had found one of these systems and in another case the other system to be the cheaper.

Laying a 16-In. Main in Portland Harbor—H. V. Fuller, chief engineer Portland Water District, described the laying of a 16-in. cast-iron main from Portland across the harbor to South Portland. Flexible joints of the improved Boston Metropolitan District type were used for every third length. The harbor water has a temperature of 28 deg. F. in winter. Cans of fresh water buried in the marshes showed that a 6-in. clay cover would prevent freezing, but it was decided to give the submerged pipe a 3-ft. cover for protection against dragging anchors.

The pipe was laid in water ranging from shallow to 45 ft. deep. For laying, a curved cradle or chute of yellow pine timber, suspended between two floating pile drivers, was used. Before the pipe was placed in the cradle, three joints were poured on a lighter lashed to the pile driver floats—one joint gave a 24-ft. section and two joints a 36-in. section. These two sections were hoisted to the pipe-laying chute and connected by pouring the joint, thus providing a 30-ft. section. After a connection had been made between the shore and the lower end of the pipe in chute, the whole rig was moved forward. Progress was by 24-ft. hitches. The cost of the job (not including pipe) was \$7.75 per lin.ft. as follows: trenching, \$2; pipe-laying, \$5; covering, \$0.75. The contractor did not make a profit commensurate with his risk. Leonard Metcalf, Boston, was consulting engineer for the work.

Selection of Pumping Equipment for Station Economy—The economics of pump selection was reviewed in considerable detail by Frank A. Mazzur, Boston, taking

one type after another. The author's data pointed to the Diesel engine as affording a high duty and being well suited to medium and small plants. In the discussion, the Diesel engine seemed to meet with general favor. Several speakers agreed that the electric-driven pump has more need of attendance than is often represented.

Worcester's Reservoirs—The nine reservoirs of the Worcester water-works were described by George W. Batchelder, water commissioner, and possible ways and means to meet the need for additional reservoirs were outlined.

Applications of the Venturi Meter—A recently discovered portrait of Venturi, high spots in hydraulics antedating and accompanying the development of the Venturi meter and an outline of progress with Venturi meter registers were presented in a paper by Frederic N. Connet, chief engineer, Builder's Iron Foundry, Providence. Among the registers described was one for use where reverse flows occur, as where water passes through a distribution system to a reservoir, then from the reservoir back into the system.

Superintendents' Session—An evening was set apart for papers and topical discussions designed to appeal to the superintendent. Two papers were read, and eight subjects listed for topical discussion. Four were taken up and the other four postponed to one of the winter meetings.

Hydrant Connections: F. A. Marston, Boston, read a paper on "Hydrant Connections for Fire Engines." There is a tendency, he said, to omit steamer connections. Against this Mr. Marston presented his own ideas and also the results of correspondence with fire underwriters, insurance, and water-works engineers, practically all in favor of at least one 4½-in. steamer connection. This may be combined with two 2½-in. outlets, or in large cities there may be two 4½- and one 2½-in. connections. The paper and discussion indicated a growing use of "pumpers" in place of the old-time fire engines, and also a tendency to lower pumping station pressures, to be made good by the use of "pumpers." The discussion also indicated a strong general opinion that fire department men do not know how to use fire hydrants and that water departments should always have men at fires to make sure there is no improper manipulation of the hydrants.

Water Hammer from a High Pressure Regulating Valve: Sydney Lee Ruggles, city engineer, Barre, Vt., recounted unfortunate experiences with a regulating valve having a very heavy unbalanced pressure. There was such severe water hammer that, year after year, weeks were required altogether to repair leaks in the pipe line. After Mr. Ruggles took charge of the works he put in a relief valve and adjusted the lever arm and float and later put on a 400-lb. weight. The final result was the almost complete elimination of the water hammer and resultant leaks.

Universal Pipe on Curves: Cement-lined wrought-iron pipe at Barre, Vt., laid as long ago as thirty-five years, is being replaced gradually with universal pipe. The flanged, machined and bolted joints on this pipe have been found readily adaptable to curves and the work has been tight.

Standard Water Meter Register: A topical discussion opened by W. C. Hawley showed that in a few

places water-works have followed gas company practice in leaving post cards, with meter dial diagrams on them, for householders to fill in and mail when meter readers find the house temporarily closed. The variety of meter dials encountered has led to an appreciation of the need for standardization of meter dials. The convention authorized the Executive Committee to revive the meter specifications committee of the Association in order that it may take up dial standardization with the similar committee of the American Water Works Association.

Brass Pipe for Services: The discussion on this topic indicated that a few works are using brass in place of steel or lead services, but the discussion ran off into the relative life of wrought-iron and steel pipe, electrolysis and other side questions.

Protection of Water Mains Crossing Bridges: A few examples were given but the consensus of opinion seemed to be that except where the circulation of water is very slight no protection from freezing is needed. The difficulty of getting an airtight protection was emphasized.

Valve Boxes at Main or Curb: No one seemed to know of any New England city except Worcester where valve boxes are set at the main (in the street) instead of at the curb and there was but little sympathy expressed for such a departure from common practice. The argument for location at the main is that by that means only can the entire length of the house service be controlled.

Supply Men Papers—Friday morning was given up to four papers which were essentially supply men or manufacturer's papers, although one dealt chiefly with steam gaging practice.

Manufacture of Wrought-Iron Pipe: A. A. Getheman, of A. M. Byers Co., showed by films the whole process of making wrought-iron pipe, from loading ore at the mines through to galvanizing and testing the pipe.

Testing, Maintenance and Operation of Large Gate-Valves: Allegations of no material improvements in the design and manufacture of large gate-valves since 1880, of careless maintenance once the valves are buried, and of serious mishaps when attempts are made to operate these buried valves were made by Payne Dean, New York City, who also described his motor-truck-mounted and motor-operated valve, opening and drainage pump equipment and his electric control system by means of which one or more valves may be closed or opened from a distant point.

Records of Steam Flow: With the substitution of local examples (New England) C. C. Covert, of W. L. & L. E. Garley, Troy, N. Y., gave much the same paper as he presented at the A. W. W. A. meeting at Detroit, last June. In general, the steam gaging methods of the U. S. Geological Survey were illustrated and explained.

Chlorine Control Apparatus: Something of the evolution of chlorination apparatus for water disinfection, and the latest improvements in this field were described by Gilbert H. Pratt, New England Agent of Wallace & Tiernan. Among the lantern pictures were two showing the largest chlorination plants in the world. These are at the Cleveland sewage-works, the latest one, recently put in operation, having a capacity to feed eight tons of chlorine in 24 hours.

New Engineering Organization on a British Railway

EXTENSIVE changes in the engineering departments of British railways have been made necessary by the consolidation of all the several lines into four great systems. The new administration and engineering organization of the Southern Ry., which is the smallest of these systems, with 2,200 miles, has been announced recently and a summary of this organization is given below:

Administration—The Board of Direction consists of twenty-one members, including the chairman, and has the following committees to deal with the various matters incident to the business of the company: (1) Law and medical, (2) traffic, (3) engineering and real estate, (4) locomotives and passenger and freight cars, (5) docks and marine, (6) stores, (7) finance and rates. The departmental system of organization comprises the following departments: (1) Executive, (2) secretarial, (3) legal, (4) accounting, (5) real estate, (6) rating, (7) operating, (8) commercial, (9) civil engineering, (10) locomotive and car construction and maintenance, (11) docks and marine, (12) electrical engineering, (13) purchase and supervision of horses (for cartage service), (14) stores, (15) medical, (16) police. All department heads report to the assistant general manager.

Engineering—The chief engineer, as head of the civil engineering department, has under him the following assistants: deputy chief engineer, chief assistant for parliamentary purposes, permanent way engineer, new works engineer, engineer of bridges and roofs; engineer for heating, lighting and water service; architectural assistant; quantity surveyor; signal engineer; telegraph and telephone assistant; and several district engineers.

The staff of the docks and marine manager includes an engineering assistant in charge of the maintenance of the works and the preparation of plans and estimates for improvements and new works. The electrical engineer is an independent officer, mainly in charge of the supervision and control of the power houses in connection with the electrically operated lines. This does not include power plants under the control of the chief mechanical engineer and the works and marine manager, but he must be consulted in regard to maintenance, renewal and extension of these latter plants. He is also to be consulted upon all questions affecting the purchase of electricity and electric equipment for power and traction on all schemes involving the employment of electricity other than those affecting signals, telegraphs and telephones.

Hetch Hetchy Water Used in Storage Batteries

For six years water taken from the Tuolumne River, which is the Hetch Hetchy source of supply, has been used in storage battery locomotives and automobile storage batteries on the project in preference to distilled water which the city formerly purchased for storage battery use. Before the change to the river water was made the city chemist made comparative analyses and placed his O.K. on the river water and after six years experience the batteries are still giving excellent service.

Large Open Air Swimming Pool at Camp Dodge, Iowa

Walls and Floor of Reinforced Concrete—Three Million Gallons Capacity—Bath House of Concrete and Hollow Tile

BY L. N. HINTGEN

City Engineer, Sioux City, Iowa

CAMP DODGE, Iowa, has recently been provided with an outdoor swimming pool which is unusual on account of its size and the completeness of its equipment. Its construction is the result of a decision on the part of the state authorities to maintain the camp as a permanent training camp for state troops. The pool is so located that it forms a nucleus around which

GENERAL VIEW OF SWIMMING POOL AND BATH HOUSE

an undeveloped part of the reservation is to be made over into a park.

It is one of the largest in the middle west, being 350 ft. long and 150 ft. wide and holding more than 3,000,000 gal. of water. When filled to the overflow the water is 2½ ft. deep at one end and 9 ft. at the other. The wading end runs to 3½ ft. deep at a distance of 85 ft., and then deepens at a more rapid rate until it reaches the diving area, where eight wide springboards form convenient jumping off places for the divers. A large float has been placed in the center of the deep water section and a diving tower located on the float. The diving tower and float may be removed to clear the water for swimming races whenever desired. The great length of the deep water makes the place ideal for 100-yd. swimming races as it provides a long straight-away before the starting line is reached.

The walls and the entire floor of the tank are of reinforced concrete. Expansion joints are provided between each 90-ft. section of the side walls and between the 50-ft. squares in the floor. The water is supplied through a 12-in. cast-iron main; the fresh supply entering at the middle of the shallow end. The outlet which is at one corner of the deep end consists of a 15-in. main which empties into an artificial pond. The overflow is immediately above the outlet, and takes the water when a continuous flow exists. The flow of water from one end of the pool to the other insures fresh, chilled water at all times. Under full pressure about six hours are required to fill the pool to its capacity, and it requires a similar length of time to empty the entire basin. The outfall water as it leaves the outlet pipe passes into an artificial channel where falls have been made by two dams of a construction resembling the natural outcropping of sandstone. There is also an artificial spring cropping out of the high embankment at the outlet. On the east side there is a natural amphitheater on each side of a road, located 100 ft.

from the walls. A fence marks the border of the road, and the interior grounds are sodded and planted with shrubbery. On the high ground toward the southeast is an electric light unit, equipped with reflectors, which will illuminate the entire site. Drinking fountains and a pebble beach have been provided.

The bath house is of hollow tile construction with stucco exterior, and a red tile roof in Spanish mission style. The floors are of concrete. The building is divided into two dressing rooms and two shower rooms. There are two locker rooms, the one for enlisted men containing 1,008 baskets, and the one for officers having 182 baskets. The dressing rooms are arranged to accommodate 2,000 persons a day. A heating plant is located in the basement. As the pool can accommodate more than 600 persons at one time it was decided to equip the bath house with 100 showers.

In the design of the tank walls the effects of earth and water pressures were assumed to act independently. Possible surcharge condition on the earth side was disregarded. Equivalent horizontal earth pressure was taken at 30 with assumed weight per cubic foot of 100. Water was taken at 62½ pounds. Variations from sections required by formula were based on requirements for watertightness, and on local soil and ground water conditions. Added stability to walls was given by the circular form chosen at the corners. These large sections being free from joints resisted horizontal forces easily. This was also found to form a means of equalizing and disposing of temperature difficulties. Thickness of walls had to be held at a minimum on account of available funds, but the dimensions chosen were ample to prevent seepage. A rough construction joint was formed at the junction of walls and footing by pulling out an irregular groove between vertical steel before final set.

The steel content averaged about 67 lb. to the cubic yard. Closely spaced small section steel was considered preferable for the floor on account of the lightness of construction. Concrete strips 4x18 in. were poured in trenches cut in the subgrade of the floor and centered under the joints to keep the asphalt filler in place.

The original specifications called for 1:2½:4 concrete, using stone up to 1½ in., with an addition of 10 per cent of hydrated lime by volume of cement. But as the stone first delivered contained undesirable particles, this mixture was changed to 1:4 made up of bank gravel containing 55 per cent of materials over ½ in. and an addition of about 10 per cent of stone. The lime added materially to the waterproof quality of the concrete. The outside of one of the deep walls was exposed to a 6-ft. stand of water after it was a week old and during five weeks showed no signs of dampness on the inside face. The same class of concrete was used for footings, walls, and floors.

The floor was poured by spouting. The lower four inches were spread before the reinforcing was placed. Then the upper 2 in. were poured, the excess water was expelled by roller, and finishing done by heavy wooden floats.

The expansion joints in the side walls were made 2 in. wide with a copper plate bent in the shape of a V set into the adjoining sections to close the opening. A steel plate closer was bolted to the first wall on each side to hold asphalt filling in place and to assist in keeping the walls in line. The bolts and anchor rods running back into the wall, and one edge of the copper,

Hints That Cut Cost and Time

For the Contractor and the Engineer

Expansion Details for Concrete Bridge Railing

BY O. W. GATCHELL

Office Engineer, Phoenix Utility Co., Sanford, N. C.

SUBSTANTIAL railings are the rule for present-day concrete bridges, and for a beam type, two-span skew structure as shown, with railings continued outward over wing-walls to the limits of the roadway, the expansion movement at end seats and center pier precludes pouring the railing entirely monolithic with rail posts and curbs.

The main feature of the railing design here shown lay in making every third post an expansion point for both sets of entering rails, intervening posts being poured integral with rails. A panel length was adopted such that the larger posts near abutments and pier were expansion points corresponding to joints between deck beams and abutments and wing-walls. The bottom rails in the two panels adjacent to each expansion post were separated from the bridge or wing-wall curb by $\frac{1}{4}$ -in. tarred felt. Freedom of movement of rails in expansion posts was secured by a tarred felt joint surrounding the sides and the end of the entering portion of the rail. The reinforcing for rails was continuous through those posts without joints.

Precast railing not being advisable for the structure in question, forms for all posts and rails on one side of the roadway were built at a time. After the shores under the bridge deck had been removed, all concrete for the side was poured except in expansion posts. Following a minimum set of four days the form construction in the interior of these posts was carefully removed from around the ends of the entering rails,

tarred felt was applied around the bottom set of rails first, and then concrete was poured up to the top rails, whose ends were similarly protected, and the pouring was completed.

By compensating for deck movement and rail expansion proper in every third post, only ten expansion posts were needed for 215 ft. of railing, thus avoiding the questionable construction of an entirely rigid railing on a multi-span bridge while saving in construction time and expense as compared to a design using an expansion joint in every post.

The design presented was developed by the writer for federal-aid work in Hocking County, Ohio.

FIG. 2—DETAILS OF EXPANSION POST

Bunk House Sterilizer Uses Live Steam and Creosote Oil

A PIECE of apparatus has been built and is being used on the Big Creek project of the Southern California Edison Co. which has been found very effective in disinfecting dormitories and bunk houses in construction camps. The device consists of a 10-hp. vertical boiler, mounted on a steel wagon frame, and is fired with wood or coal, building steam pressures up

PORTABLE STERILIZER FOR USE IN CONSTRUCTION CAMPS

FIG. 1—LOCATION OF RAILING EXPANSION POSTS

to 110 lb. per sq.in. An old locomotive air compressor mounted on one side of the boiler is used to maintain a pressure of about 90 lb. per sq.in. in a reservoir fastened to the wagon frame on the opposite side of the boiler. A 10-gal. tank also attached to the wagon frame is used as a storage tank for creosote oil. Air pressure is admitted to this tank so that the creosote can be forced out as desired.

The device is arranged for operating two hose lines, one direct from the boiler for the use of live steam, and the other fitted with a combination nozzle taking air pressure from the air reservoir and creosote from the storage tank, the arrangement of the nozzle being such that the creosote oil is delivered in a fine spray.

Steam may be substituted for the compressed air in the combination nozzle.

When a building is to be treated by this method all contents are removed, including building paper or other wall coverings. The base boards, door, and window frames are also loosened. The entire interior is then given a thorough treatment with live steam, special attention being given to cracks and corners. Next, all surfaces are given a light coating of creosote oil by using the combination nozzle. After drying for 24 to 48 hours, according to atmospheric conditions, the building is ready to be re-equipped for occupancy.

The live steam kills all vermin and eggs, and the creosote oil, which impregnates the wood, tends to prevent the re-entrance of pine bugs or vermin. While the creosote jet is being used a fine vapor of creosote oil fills the building and if left closed it is untenable for several hours. Operators must wear gas masks and can work only for short periods. The machine is towed from job to job by motor truck and requires three men in its operation: a fireman, operator, and helper.

Laying Pipe in Unstable Soil

By MCKEAN MAFFITT

Superintendent, Department of Public Works, Wilmington, N. C.

IN CUTTING an open ditch recently for drainage purposes such unusual soil conditions were encountered that it became necessary to use large concrete pipe and

then refill the ditch. The soil proved so unstable that backfilling became necessary as each short section of pipe was laid.

The average depth of cut was about 8 ft. with side slopes of 1 to 2. For about 5 ft. of the depth a stiff yellow clay was encountered which was most stable, but underneath this was a stratum of oozy blue clay which the upper layers of stiff clay forced out into the excavation, thereby throwing the ditch out of alignment and filling it up. In some instances the ditch filled 3 or 4 ft. overnight, and the sides settled nearly as much, leaving berms at the excavation's sides from 2 to 5 ft. wide.

To lay the pipe a 12x12-in. timber set upon a track was placed across the ditch. Lengths of pipe were lowered by a chain hoist suspended from the timber. The excavation was made large enough for the pipe, with an allowance for sliding. After the pipe was picked up by the improvised traveling crane and moved

to within 4 ft. of final location the final excavation was made and the pipe lowered to grade and immediately covered with enough mud to hold it in place. In several instances the movement of the ground was so rapid that the crane settled with the banks and the process had to be repeated.

The usual day's run was from four to five lengths of pipe with one foreman and nine workmen, but in some cases the sliding of the earth was so troublesome that not more than one length of pipe could be laid.

Light Gantry Used in Transferring Batch Boxes on Road Job

CONSTRUCTION of a 10½-mile concrete road in North Carolina, known as State Aid Project No. 533, involved some rather unusual difficulties due to the fact that the only available materials shipping point was one mile from the end of the road. This necessitated unloading of all concrete materials at a siding near where the job began and hauling preproportioned batches in steel boxes on motor trucks and trailers over as much of the concrete road as was opened to traffic and then transferring the batch boxes to industrial cars for transportation past the new pavement to the mixer.

In order to avoid turning the trailer around, the truck-trailer unit ordinarily continued past the aggregate bins and drew up at the cement shed, where four bags of cement were placed in each batch box on the truck. The truck was then uncoupled from the trailer and driven to the aggregate bins, where stone and sand were added. Meanwhile cement had been placed in the batch boxes carried by the trailer. The truck then backed up to the cement house, and was coupled to the other end of the trailer, which was then pulled up to receive the aggregates.

"Do you remember—"

Weather conditions will soon drive construction men and engineers, who have been working long hours on a thousand projects throughout the country, indoors. Reminiscence will replace actual experiences: and numberless conversations during the coming winter months will begin with:

"Do you remember—"

In many instances the query will doubtless recall a particularly hard job solved through someone's ingenuity or quick thinking. *Engineering News-Record* invites its readers to translate such reminiscences into "copy." Potential *Job and Office* articles are frequently contained in a conversation which begins with:

"Do you remember—"

LEFT—IMPROVED GANTRY HANDLES PIPE LENGTHS
RIGHT—GENERAL VIEW OF DITCH

The stump in the foreground moved horizontally 3 ft. in one night. The berm at the side is about 3 ft. deep, and was formed the same night.

With paved streets and the concrete road to haul over, the trucks made good time en route to the transfer station where they stopped under a light gantry crane which carried a pneumatic hoist. The gantry spanned the concrete slab and the track of 24-in. gage along the shoulder. Lifting tongs suspended from the hoist were hooked into holes at the sides of the batch boxes, and they were quickly lifted and moved sidewise to position over an industrial car truck. When enough boxes had been transferred to make up a train load, the cars were pulled to the mixer by a gasoline locomotive.

According to a recent issue of *Concrete Highway*

GANTRY MOVES BATCH BOXES FROM TRUCK TO TRAIN

Magazine, eight cars, each carrying two boxes, was a standard train, though on grades, of which there were several ranging from 3 to 5 per cent, the train length was cut as low as five cars.

The work was done by the Royer-Ferguson Co., Inc., of Roanoke, Va. John D. Waldrop, of Greensboro, N. C., was district engineer in charge of the work for the state.

Welded Tank Joints

A PROCESS of electric welding in the field for the joints of the large steel plates used for the bottoms and roofs of oil storage tanks is a new development in tank work which is being introduced by the Chicago Bridge & Iron Works, Chicago. For an ordinary 80,000-bbl. tank, 117 ft. in diameter, the $\frac{1}{2}$ -in. bottom plates are

WELDING STORAGE TANK

From Job and Office

Hints that Cut Cost and Time

about 19x6 ft. These are assembled on a leveled surface and tack-welded to hold them in position while the regular welding is being done. The operation is said to be quicker than riveting and more fully to insure oil-tight joints. In the roof also, usually of $\frac{1}{2}$ -in. plate, it is easier to secure gas-tight joints for the roof itself and for the connection of the roof to the shell. Test specimens are said to have shown ample strength, and in tests continued to failure the break is often through the solid metal instead of at the welded joint. Around the tank bottom is welded an angle-iron ring, to the upstanding leg of which the first course of shell plating is riveted. In the same way the roof is welded to an angle-iron ring on the top of the shell. With the tank bottom laid on the ground for welding, it cannot be tested by filling with water after the first shell course is placed, as is done with riveted tanks in which the bottom is built on blocking to permit of bucking

Up-ended Barge Moved 43 Miles by Rail

A BARGE, built to be used in dam construction on a stream flowing into Lake Labarge, Alaska, was recently moved 43 miles by rail. Being 21 ft. x 60 ft. in size the barge had to be up-ended as shown herewith. It was braced by 8 x 8-in. timbers resting on cantilevered beams, three braces being placed on each side of the barge. Additional ties were provided through use of rope lashes and turnbuckles.

up the rivets from below. As an alternative, oil is pumped under the tank bottom and though only a light pressure can be obtained in this way, the method is considered sufficient to develop any leaks.

Radiation Reduced by Aluminum Paints

The aluminum or bronze paint generally applied to radiators greatly reduces their effectiveness and makes it necessary to have a larger surface for the same heating effect, according to experiments performed by Dr. W. W. Coblentz of the Bureau of Standards. Dr. Coblentz finds that the heat radiated from an aluminum painted radiator surface is less than a third of that emitted by a radiator of the same size painted with a non-metallic paint, enameled, or simply allowed to rust

Finding Yardage in Circular Excavations

BY W. F. SCHAPHORST
Newark, New Jersey

THE CHART herewith will be found convenient for quickly estimating the number of yards to be removed from any ordinary sized circular excavation. To use the chart simply run a straight line across from Column A to Column C and the number of yards is immediately given in Column B. For example, the chart shows 8,700 cu.yd. for an excavation 30 ft. deep and 100 ft. in diameter. The correct answer, making the actual computation, will be found to be 8,720, showing that the chart is surprisingly accurate as well as quick.

CHART GIVES EXCAVATION YARDAGES

The range of the chart as will be noted, is very great. It will take care of any depth of excavation from 1 to 300 ft. and any diameter from 3 to 1,000 ft. The maximum number of yards is 8,000,000.

The chart can be used as well for determining cubic contents of cylindrical tanks.

Bridge Fills Temporary Construction Use

TO transport material from the river bank to a cofferdam on a hydro-electric project at Gorham, N. H., the contractor, the Sanders Engineering Co., of Portland, Maine, constructed this simple suspension bridge.

Transporting 68-Ton Girders for a Chicago Building

ALMOST the largest steel girders ever hauled into the business district of Chicago for building construction were two 68-ton plate girders which were moved from railroad yards to the site of the new Straus Building at Jackson and Michigan Aves., on Sept. 9. These girders, which will be placed between the fifth and sixth floors and will support the steel frame over the main entrance, are 55 ft. long and 11½ ft. deep. It took practically all day to unload the girders from cars, transport them about half a mile and unload them at the building site.

A railway wrecking car of 150 tons capacity was used by the Chicago, Milwaukee & St. Paul Ry. to load the girders on flat cars at the Goose Island yard for transfer to the team yard of the Michigan Central R.R. at Michigan Ave. and South Water St. There a wrecking crane of the Illinois Central R.R. picked up each girder in turn, as shown in Fig. 1, and placed it on a special combination truck. This truck, shown in Fig. 2, consisted of a heavy drop-frame truck having its front end carried by the rear of a four-wheel tractor and having coupled on to its rear end a trailer with four wheels in a row on two short axles. Wide tires were used on all the eight load-carrying wheels, with ordinary tires on the front wheels of the tractor. About 42 tons or 62 per cent of the total load was carried by the trailer. For hauling such loads it has been usual to employ teams of 50 to 70 horses, but in this case two tractors rated at 40 hp. each were used. These tractors were placed side by side. One was an integral

FIG. 1—WRECKING CRANE HANDLES 68-TON GIRDER

part of the truck and the other was attached to the truck by a heavy chain.

It is stated that the only heavier girder handled in Chicago was a 70-ton girder for the Stevens Building. Two 63-ton girders were used in the Chicago Theater. The 68-ton girders were built by the Phoenix Bridge Co., Phoenixville, Pa., and will be erected by the Thompson-Starrett Co., which has the general contract. This company is using two large steel guyed derricks with 125-ft. masts and 115-ft. booms in the erection of the steelwork of this 32-story building for S. W. Straus & Co. These derricks swung the girders from the truck and will place them in position later.

The transportation of the girders was handled by the Pennoyer Merchants Transfer Co., Chicago.

Hints that Cut Cost and Time

Cost of Ballast Cleaning: Santa Fe Ry.

FIGURES from work done with five of the Harris-Muff ballast cleaning machines on the Atchison, Topeka & Santa Fe Ry. indicate a cost of 25c. per cu.yd. In the accompanying table the cost is given per mile, and it is estimated that the ballast cleaned would approximate 2,500 cu.yd. per mile. This machine, described in *Engineering News-Record* of March 8, 1923, p. 468, consists of a rotary screen mounted on a small car and driven by a gasoline engine. Men shovel ballast from the track into a long trough having a belt conveyor which delivers it to the screen. The cleaned stone passes out through a chute to the track while the dirt goes to a lateral belt conveyor which discharges it clear of the track.

The work shown in the table covers a little over nine miles and represents an average section of 12 in.

COST OF CLEANING BALLAST BY MACHINE

Division	Mile of Ballast Cleaned	Both Sides and Between Ties, Depth, In.	Average No. of Men in Gang	Total Cost	Cost per Mile
Eastern.....	2 73	9	18	\$1,788.76	\$655.22
Middle.....	1 77	12	16	943.45	533.02
Western.....	1 70	14	21	603.27	354.80
Panhandle.....	2 41	12	50	1,231.49	510.98
Albuquerque.....	0 52	8	18	997.77	1,918.79
Total or average	9.13	12	20	\$5,564.74	\$609.50

of stone ballast. The ballast between ties to level of bottom of ties and that on both shoulders was cleaned and replaced. No complete records have been kept of the cost of cleaning ballast by hand labor, handling it with forks, but it is estimated that this hand work costs about \$1,500 per mile.

Removing Rails and Restoring Paving at Everett

THE PUGET Sound International Railway & Power Co., operating the local transportation system in the city of Everett, Wash., completed in the month of August the removal of 10 miles of single-track line which has been superseded by motor buses. The city ordinance permitting the company to remove these rails has required that the paving be so restored that after the removal of the rails the portion of the street where the track formerly was located should have a surfacing equally as good as that in the remaining part of the street. The reconstruction of the paving has been done by a single crew divided into squads which followed one another closely so that a minimum length of the street would be torn up at one time.

The first or advance squad consisted of several men using picks, claw bars and shovels. The header bricks outside the rail were not disturbed, but the bricks on the inside were removed, spikes on the inner side of the rails were pulled, and the rails were removed and placed on the pavement alongside. All debris and loose paving was removed and piled on the street and the channels thus left in the pavement were brushed clean ready for surfacing material. The work of this crew was supplemented by trucks which hauled away the rails and piles of debris.

Following this advance squad came a four-man concrete crew with a small portable mixer pouring concrete into the trenches left by the removal of rail and brick. These trenches varied in width but averaged about 18 in. Where the ties were imbedded in concrete they were not removed and hence the depth of the trench was the same as the rail height. In pouring concrete in the trenches a $\frac{3}{8}$ -in. tarred paper joint was put in at right angles to the street center line every 15 ft.

Where necessary, and this constituted a large part of the reconstructed pavement, a three-man asphalt crew followed the concrete squad, using a portable tar kettle and tool-heating rack. The work of this crew was chiefly with square-nosed shovels and hot irons patching small depressions or worn places in the line of header bricks or other parts of the surfacing.

Laying Pipe-Line Under Panama Canal

A 20-in. pipe to carry water from the Rio Grande reservoir to the east bank of the Panama Canal under the Pedro Miguel locks developed a serious leak in April. As the line was embedded in the concrete of the locks the leak could not be located and repaired without keeping the west lock unwatered an indefinite time. In consequence a new line in another location at Paraiso, where formerly the pontoon bridge of the Panama R.R. crossed the canal, was chosen. Cast-iron screw pipe, 12 in. in diameter and 459 ft. long, was assembled in one section on the pontoon of the former bridge and dropped into a trench 5 ft. deep and 25 ft. wide. The ends projected out of the water at each bank and, according to the *Canal Record*, were found tight on test.

Drawings Which Fold to Letter Size—George C. Love, of Newport News, Va., submits a detail of office routine that should prove interesting to those who have in charge preparation of plans which must accompany letters to be sent through the mail. Often odd-sized maps arrive at their destination in bad condition, due to the fact that folding was of a hit or miss nature. Mr. Love finds that by employing the following outside dimensions, maps fold naturally into an 8½x11-in. sheet; 42½x55 in., 34x44 in., 25½x33 in. and 17x22 in. The title is at all times to be found in the lower right hand corner, and the blueprints are to be folded in such a manner that the title card is always visible.

Well Water Level Indicator With Telephone Attachment—Referring to the article in the "From Job and Office" section of *Engineering News-Record* last week, describing a method of discovering the water level in a well by means of a pocket electrical device, S. P. Baird, engineer with The Jennings-Lawrence Co., civil and municipal engineers of Columbus, Ohio, has suggested that a variation of these devices, two of which were described in *Engineering News-Record* several months ago, is secured by the use of an ordinary telephone receiver, high and low resistance coils, and a vibrator. Instead, therefore, of having to watch to discover when the water surface is reached, when the exposed end of the wire touches the water the telephone emits a sound like an auto horn. The sound from the receiver can be stopped or started by raising or lowering the wire $\frac{1}{8}$ in.

Removing Old Tramway Standards

Removal of old trolley-wire standards may often necessitate breaking up by hand the concrete blocks in which they are usually embedded, but a more effective method is removal by means of two small hydraulic jacks and a portable hydraulic pump as described by an English correspondent. Referring to the sketch: Bearer-plate *a* is bolted to the standard at a suitable height from the ground and under each end of this one of the jacks is placed as shown at *b* and *b'* on two short lengths of I-beam, *c* and *c'*. Forcing water into the rams causes the pole to be ripped out of its foundation but in a steady noiseless manner and when the full stroke of the rams is reached the bearer-plate is lowered down the standard and the process repeated.

Welding Lugs on Sections of Artesian Well Casing—Instead of the usual screw joints used in connecting sections of artesian well casing, a contractor drilling a well in New Jersey recently conceived the idea of applying oxyacetylene methods of welding lugs to pipe sections. The well required nine 20-ft. lengths of steel pipe 18 in. in diameter with walls $\frac{5}{16}$ in. thick. In accordance with plans worked out in the shop, four lugs 1½ in. x 8 in. x ½ in. thick were welded on the outside of one end of each section of pipe with half the length of the lug extending beyond the length of the pipe. The lugs were so fastened that a pipe section fit inside of the next successive section, holding the pipe in a perpendicular position while being sunk. This suggestion for artesian well contractors is contained in a recent issue of the house organ published by the Linde Air Products Co., New York.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Shaded Topographic Maps

Sir—An erroneous impression is given in your issue of Sept. 6, 1923, p. 382, that there is something new in the idea of a shaded topographic map. It may be new to the Geological Survey but not new to the Corps of Engineers. The current issue of *The Military Engineer* contains an excellent description by Major A. M. Walker of the work now being done at the engineer reproduction plant at Washington in the production of contour maps with shaded relief and an account of French army map work as developed during the war. The French army maps of 1912, scale 1:200,000 printed in four colors, use shading to bring out the relief as shown by contours. The new series of eastern France, scale 1:50,000, begun in 1914 and not completed by 1918, show the same system much improved and permit an excellent visualization of the terrain.

They give also, what the Geological Survey maps omit, all forested areas in green as well as cultivated areas shown by appropriate marking, thus conveying much more information to the map user than can be obtained from any maps available in this country.

Admitting all the well-known reasons why our country has not yet been mapped as thoroughly as Europe, there should be no reason why our present mapping should not equal theirs in quality. Perhaps a little team-work between different government departments could help out. At present it would appear as if the War Department could give a tip or two to the Geological Survey. It certainly could in the use of durable paper.

Sandwich, Mass.,
Sept. 15, 1923.

HENRY WELLES DURHAM,
Lt. Col. Engr. O. R. C.

[It was not our intention to give the impression that the shaded topographic map was new to either the Geological Survey or to the Corps of Engineers, for it is our belief that both these agencies have been working on this type of map since war days. What we did wish to do was to draw the attention of engineers in general to the shaded topographic map as a new type of U. S. G. S. map in order to draw out some constructive criticism for the benefit of the Geological Survey.—EDITOR.]

Concrete Borers Not Active

Sir—During the current year a number of articles concerning "concrete borers" have appeared in the technical press. The subject is of general interest to the public because concrete is considered one of the best examples of a hard, enduring, all-resisting material; consequently we find references to the borers appearing in numerous non-technical magazines and newspapers.

There has been a wide range in the interpretation of the extent of the observed work of the borers. The most pessimistic would have it that all concrete is doomed when placed in water infested with them. The writer recently had the opportunity of inspecting concrete at a number of points along the coast of California and is very optimistic concerning this threatened scourge of concrete in sea water.

At La Jolla near San Diego there is a concrete pier at the Scripps Institution for Biological Research. This should be an excellent place to obtain information, but inquiries revealed that while the borers are numerous in the locality and can be easily located in the shale cliffs none have ever been found in the concrete.

At San Pedro the borers are found in only one locality in the harbor and the writer was told that considerable time would be required to find any of them.

The borers are known to be present in San Francisco Bay, but according to engineers of the California Harbor Commission no concrete has been found attacked by them. Chicago, Sept. 10, 1923.

J. C. WITT,
Structural Materials Research Laboratory.

The Right Way to Help the Japanese

Sir—I wish to voice my hearty approval to your note to Dr. Waddell's letter published in the issue of Sept. 6, 1923.

My experience in France and Italy during the late war and the personal contact I had with engineer and architect refugees from the invaded zones lead me to think that having passed the first short period following the calamity our colleagues' desire is not to have the little financial help which the more fortunate colleagues can give, but opportunity to work and provide their own livelihood.

It seems to me the Japanese have plenty of work in their own country provided they have the means to go ahead with the rebuilding of their devastated cities. What they will need most are the materials and machinery for their work.

It is admitted that most of the materials and machinery will have to come out of the United States. And here is where we engineers, manufacturers and dealers on these goods can help them, and helping them help ourselves with no injury to anyone.

We note already an increase in price of the very goods most needed.

Here is where we can serve. Let us sound a clarion note to be heard all over the world that any increase of price in the line of goods needed in Japan is not justified by any economic reason but is the consequence of the greed of the manufacturers, merchants, and transportation companies, and will result in defeating our noble purpose of helping Japan and be very serious to our industries.

With the exception of wheat there is ample margin of profit with the present prices, and this profit will be greatly increased with the increase in the volume of business. Let us distribute our production throughout the entire year. Let us take advantage of this opportunity to fill in the gaps on the production year, and everybody will be better off, and we shall surely help not only our Japanese colleagues, and their fellowmen, but our own people as well.

I am tempted to comment more fully on this topic, but I think I have said enough. Let us work hard at it in true patriotic American spirit.

Birmingham, Ala.,
Sept. 15, 1923.

FRANCESCO MAURO,
Engineer and Architect.

Water Economy of Ash Pits

Sir—Referring to the abstract of report of the A.R.A. committee on Engine Terminal Design, page 424 of the Sept. 13 issue of *Engineering News-Record*, there has been a great deal written, published and read before societies in recent years about railroad terminal design, dwelling largely on capacity, equipment and economy, describing in detail the design of terminal, enginehouse, turntables, coaling stations, cinder pits, etc., but not a word on an economical water service to cinder pits.

Why stop part way on the subject of economy? Do the engineers and designers know the difference between an economical cinder pit hydrant service and a wasteful layout? There is a difference and a big one and I am sorry to say from twenty years of close observation of this subject that very few do. True, most engineers know that all water to railroad terminals is metered, but that does not mean that the meter is considered—waste goes on regardless because of the absence of a preventive.

I know of many instances, one in particular, where the water engineer put his economy program into effect down to the smallest hydrant, including the cinder pit hydrants, and caused a saving of some \$30,000 in metered water in the city of Chicago. This same practical water-works engineer extended that hydrant economy program to all parts of his road with an unprecedented record in economical water service.

Stapleton, N. Y.,
Sept. 15, 1923.

WILLIAM VOLKHARDT,
President, Volkhardt Co., Inc.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

Four Killed in Explosion at Bureau of Standards

Washington Correspondence

No official information is yet available as to the cause of and the responsibility for an explosion in the dynamometer laboratory of the Bureau of Standards on Sept. 20, resulting in the death of four employees and injury to six. The coroner's jury pronounced the death of the victims to have been due to "an accidental explosion of gasoline and air mixture in the altitude chamber."

The dead are Logan L. Lauer, assistant physicist; Urvan J. Cook, machinist; Stephen M. Lee, mechanical engineer; J. E. Kendig, assistant electrical engineer. Among the injured Herbert K. Cummings, an associate physicist, continues in a critical condition.

An exhaustive investigation of the accident is proceeding as rapidly as possible but no announcement will be made until the investigation is completed. It is expected, however, that the investigating committee will find that the cause of the accident was due to leakage of gas fumes from the engine that was being tested.

Secretary Hoover referred to the dead as "martyrs to science." The damage done to the building can be repaired for less than \$10,000. No important delay will take place in the testing of airplane engines.

It is pointed out that this accident will tend to emphasize the importance of the resolution adopted by the executive board of the American Engineering Council at its meeting in Cincinnati on March 23. In that resolution, it was pointed out that the government "is paying heavily in the form of employees' compensation, as well as in loss of time and efficiency, for its failure to adopt a thorough-going safety program." Attention is called to the fact that the government falls far short of the standard set by many private employers, the more progressive states and some of the municipalities. Federal safety standards were drawn up during the war, but there is no officer having the authority to enforce such standards, the resolution states.

Federal Permits Granted for Two San Francisco Bay Bridges

Permission has been granted by Secretary of War Weeks for the construction of two vehicular bridges across the lower end of San Francisco Bay, one to Frank Eldridge Webb, to have its western end at Little Coyote Point, and the other to John Lyle Harrington for a bridge at Dumbarton near the site of the present railroad bridge. Franchises for both these bridge projects have already been granted by San Mateo County. A résumé of the discussion about the two bridge sites was published in *Engineering News-Record*, Sept. 7, 1922, p. 411.

Steel Frame and Reinforced Concrete Structures Survive Japan's Earthquake

Refugees Arriving in Seattle Sept. 16, Tell Special Representative of "Engineering News-Record" Details of Disaster

By W. A. GLEASON

Port of Seattle Commission, Seattle, Wash.

When it was learned that the first refugees from the earthquake-stricken cities of Japan were due to arrive in Seattle, Wash., Sept. 15, "Engineering News-Record," through the co-operation of George F. Nicholson, chief engineer of the Port of Seattle, arranged with W. A. Gleason, a member of his staff, to board the "President Jefferson" as soon as she should dock and secure from such engineers as might be among her passengers information regarding the effect of the quake on the engineering structures in Tokyo and Yokohama. Mr. Gleason undertook this assignment as the special representative of this journal; his report follows.—EDITOR.

FOLLOWING the receipt of your telegram on Sept. 12, I made arrangements through the traffic manager of the Admiral Oriental Line to meet the ship *President Jefferson* due to dock in Seattle, Sept. 15, with the first group of refugees to reach the United States from the cities of Japan devastated by the earthquake of Sept. 1. On Sept. 14 I lunched with an American engineer who returned from Japan in 1920. He acquainted me with the geography of the territory in the earthquake zone and with the character of some of the engineering structures.

Real Progress in the Development of the Port of New York

The second joint hearing of the Interstate Commerce Commission and the Port of New York Authority at which the railroad companies having terminals on the west side of the Hudson River at New York were called upon to show cause why the port authority's proposed marginal railroad on that side of the river should not now be made effectual, has ended in an unexpected and promising way. From an attitude of being openly hostile to the proposed belt line at the hearing last spring the railroad companies have come forward with a plan for operating it and have outlined certain improvements in the existing tracks which they think should be made. This change of front made a continuation of the hearing unnecessary at this time, consequently it has been indefinitely postponed while the railroads and the Port Authority get together and outline the manner in which the belt line will be made up and operated. The details of the proposals of the railroads and their relation to the plan of the port authority will be given in next week's issue.

Additional information was secured from Mr. Shivagaki, Seattle manager for Mitsui & Co., Ltd.

The *President Jefferson* was reported due at Seattle at 11.30 p.m. Sept. 15. I reached the dock at about 10 p.m. where I learned that the boat was expected to arrive about 3.30 a.m. Sunday, so I returned home for a few hours' sleep and was back at the dock at 7 a.m., before the refugees not on stretchers came off the ship. I passed the outer guard successfully but the guard at the gang-plank insisted that none could pass without a permit from the manager or the customs collector. The manager was not there as agreed, but by interviewing one of the refugees I learned the name and room number of "just the engineer you want." I was permitted to send a message to him, with the result that he promised me an interview the following day. He was too busy that day with another engineer in connection with a hospital for the wife of one of them. However, I met both of these engineers and also a college professor who was hurrying to make train connections. Although provided with a list of all engineers aboard and although I approached each person as he had his baggage inspected, I did not meet more than the aforementioned three. Sunday evening I was granted an interview with the two engineers in a local hotel. The following notes summarize their statements regarding the effect of the earthquake in Yokohama and Tokyo:

IN YOKOHAMA

The reinforced-concrete skeleton of the Russo-Asiatic Bank Building, three stories high, remained after shedding its coat of stone and brick. The heavy timber and stone Thomas Cook & Son Building was completely wrecked and every human being within lost.

The masonry walls of many buildings withstood the earth shocks while their floors and roofs were precipitated to the ground.

The six-story Telephone Building with steel skeleton frame withstood the earthquake.

The breakwater in the harbor disappeared except its ends, which remained with their lighthouses erect.

A dock with reinforced-concrete deck lost about 4 mile of its length, while about 600 yd. remained standing. The details of the underpinning of this dock were not observed.

A reinforced-concrete locomotive roundhouse remained standing and without a noticeable crack, while across the turntable the earth was badly fissured and sunken.

Binghamton Brick and Tile School Building Fails

Investigations May Show Removal of Supports Under Green Concrete, or Weak Tile Wall, to Blame

Special Correspondence

The Daniel S. Dickinson School, a 40-room, three-story grade school under construction at Binghamton, N. Y., failed just after workmen had left in the afternoon of Sept. 18. The portion of the building which collapsed included an area in plan about 60 ft. x 75 ft., comprising the external wall and two interior walls from the roof to the basement. Estimates of damage have been placed anywhere from \$20,000 to \$80,000.

Rudolph P. Miller is investigating the failure for the city authorities. Investigations to date from others have tended to narrow possible failure to two causes: premature removal of wooden supports from under fresh roof concrete, and structural weakness of one of the interior tile bearing walls. The supports for the concrete floors and roof consisted of two 2 x 4-in. pine timbers, spiked together in the form of "Ts" and spaced on an average of 4 ft. 6 in. across the rooms and 5 ft. 6 in. along the rooms, each support thus carrying about 25 sq. ft. of roof or floor. The supports were from 13 to 15 ft. long and were supported at about mid-height by 1 x 8-in. braces in each direction. They were capped along the long dimension of the room by 2 x 6's. About half the supports under the green roof concrete had been removed prior to the pouring of the roof.

If failure occurred in any of the interior walls it was probably in the first wall inside the enclosing wall. This wall was 26 ft. in from the exterior wall and parallel to it, and was of 12-in. tile. It was pierced by numerous openings as shown in the accompanying figure. It also included the rather peculiar feature of a 30-in. concrete girder resting on it and extending partially along its top. The failure was so complete it will be difficult to decide which of these causes may have been responsible, if either.

CAUSE YET UNKNOWN

No definite decision as to the cause of the failure has yet been reached due to the completeness of the failure and the danger of further collapse of portions of the front wall. Workmen refuse to start the demolition from scaffolds of such portions of the front wall as remain standing and the city is unwilling that any more wreckage be added to the mess in the building until every effort has been made to establish the responsibility. The contractors will attempt to remove the dangerous portions of the wall by means of derricks.

Exterior walls of the building were of interlocking tile with a brick facing and interior walls were of tile. Exterior walls were 16 in. thick from the basement to the first floor and 12 in. thick from there to the roof. These thicknesses included the brick facing. Interior bearing walls were 12 in. thick, except for one 8-in. wall extending from the second floor to the roof. This 8-in. wall was not completed when the failure occurred. Specifications provided that these walls should be laid up in cement mortar and that in por-

Bayonne, N. J., Rejects Proposal for Shipping Terminal

The \$150,000,000 shipping terminal and industrial center proposed for Bayonne, N. J., has been rejected by the board of city commissioners on the ground that the bond offered by the New York Port Terminal Co. is inadequate. The project has received considerable publicity as it is reported to be backed by William B. Franklin, brother of P. A. S. Franklin, president of the International Mercantile Marine; Gen. William M. Black; and William Coyne, vice-president of the du Pont de Nemours Co.; John G. Gray of Wilmington, Del.; and Henry J. Hemmens of New York.

The objection to the bond is made on the basis of the fact that under the proposed agreement the city is required to issue \$20,000,000 worth of bonds with an annual interest rate of \$1,200,000 and that the bond offered by the company would only pay this interest for a few months in case of default.

tions subject to heavy bearing the tile should be filled with concrete or the space laid up with brick. A subsequent agreement required the brick veneering to be bonded into the tile by a header course every seven courses.

Floors of the building were of the steel-pan concrete type, the pans being 10 in. and 12 in. and covered with a 2-in. concrete slab. Over the corridors

ELEVATION OF INTERIOR WALL BEFORE FAILURE

the pans were being removed for the most part for reuse. At the time of failure the first floor had been placed about three months and the second floor about six weeks.

Proposals for the construction of the school were received by the City on December 20, 1922. Five contractors submitted figures for the general construction work, the bids ranging from \$329,700 to \$426,700. The work was awarded to the low bidders, Kirkpatrick and Stento of Binghamton, their proposal being \$26,255 under the next lowest figure. Construction was started early in the Spring and the work was progressing in a fairly satisfactory manner.

The building was designed by Dickerman and Bartoo, Binghamton architects, and the building was being constructed under their supervision.

Convention of New England Water Works Men

Forty-Second Meeting Held at Burlington—Business Proceedings—David Heffernan President

Engineering News-Record Staff Report

After a lapse of 28 years the New England Water Works Association met last week for the second time at Burlington, Vt. About 400 members and guests were registered. The Water Works Manufacturers Association provided an all-day visit to Au Sable Chasm, reached by boat across Lake Champlain.

At the opening session honorary membership was conferred on John R. Freeman. The Dexter Bracket medal was awarded to Charles W. Sherman, of Metcalf and Eddy, Boston, for his paper on "The Proper Term for Which Water-Works Bonds Should Run"—printed in the *Journal* of the association last December.

The tellers' count showed that 419 ballots had been cast and that the principal officers elected were: President, David A. Heffernan, Milton, Mass.; vice-presidents, Theodore I. Bristol, Ansonia, Conn., and Stephen H. Taylor, New Bedford, Mass.; and treasurer (re-elected), F. I. Winslow, Framingham, Mass.

PRESIDENT'S ADDRESS

The chief feature of the address of the retiring president, Percy R. Sanders, Concord, N. H., was the experience of the association as one of the nine organizations composing the Affiliated Technical Societies of Boston. Before the affiliation the association employed an assistant to the secretary, at a salary of \$1,200 a year, and rented quarters in Tremont Temple, Boston, at \$750 a year, making a total of \$1,950 for these two items. Since the affiliation the assistant secretary has been clerk of the affiliated societies and is paid by that organization. The headquarters are unchanged. The association pays to the affiliated societies \$3 per member with adjustment for duplicate membership. For the year ended May 31 these payments totalled \$1,983 as compared with \$1,950 previously paid for rent and assistant secretary.

The membership of the association was 1,043 on Jan. 1, 1917 and on Sept. 1, 1923, it was 769, a loss of 274 members. During the year the association lost by death Rudolph Hering, honorary member, and Lewis M. Bancroft, treasurer.

SECRETARY'S REPORT

The report of the secretary, Frank J. Gifford, Dedham, Mass., showed a net membership loss of 59 during the eight months ended Sept. 1. Some of this loss is due to the annual dropping of members for non-payment of dues which will be partly made up before the full calendar year has been completed. The association year begins Sept. 1 instead of Jan. 1 under recent changes to the constitution. The report of F. I. Winslow, treasurer, showed a substantial balance both in ready cash and in invested funds. The net cost of the *Journal* for the year according to the report of Henry A. Symonds, editor, was \$341.

The technical proceedings of the convention will be found on p. 515.

Am. Soc. C. E. Announces Fall Meeting Program

Highway Engineering Transport and
Port Problems Are Chief
Topics of Discussion

Highway engineering and transport problems and special sessions by the power and highway divisions of the society, together with a full discussion of Norfolk's port problems and the development of Hampton Roads, Va., comprise the technical features of the fall meeting of the American Society of Civil Engineers to be held in Richmond, Va., Oct. 17-20. Not all of the time will be spent in Richmond as excursions have been planned to include Norfolk and Washington, D. C., Oct. 19 and 20. In addition to the technical discussions, there are the usual social features, and numerous excursions to various points in historic Virginia have been planned.

The morning session on the first day will be called to order by James A. Anderson, associate professor of civil engineering of the Virginia Military Institute, who will be followed by Governor E. Lee Trinkle, who will give the address of welcome. A response by Charles F. Loweth, president of the society, will follow.

GROUP OF HIGHWAY PAPERS

The following highway papers will be delivered: "Fundamental Principles of Highway Financing," by Thomas H. MacDonald, chief, Bureau of Public Roads; "Road Service in Industrial Regions," by George E. Hamlin, of Hartford, Conn., superintendent of repairs of the Connecticut Highway Department. Various short discussions will follow these speeches.

C. M. Upham, chief engineer of the North Carolina State Highway Commission, will read the principal paper at the meeting of the highway division in the afternoon of Oct. 17. "Development of State Highway Systems" will be his topic. At the meeting of the power division at the same time, "Interconnection of Southern Appalachian Power Systems" will be the principal paper and will be read by W. S. Lee, of Charlotte, N. C., chief engineer of the Southern Power Co. and of the Quebec Development Co.

WILL DISCUSS NORFOLK'S PORT

The morning session on Oct. 18 will be given over to the following papers: "The Port Problems of Norfolk and Vicinity," by Homer L. Ferguson, president of the Newport News Shipbuilding & Drydock Co.; "Norfolk's City Plan in Relation to Its Port Development," by George B. Ford, New York, president, National City Planning Conference; "The Railways' Part in the Development of Hampton Roads," by Charles S. Churchill of Roanoke, Va., vice-president of the Norfolk & Western Ry. Following these will be given a paper on the "Program and Results of the Research on Structural Design of Roads by the Bureau of Public Roads," by A. T. Goldbeck, in charge of tests, U. S. Bureau of Public Roads, Washington.

On the trip to Norfolk and Washington stops will be made at Norfolk Army Base, Hampton Roads Naval Base, including the submarine base, the training station, the aviation station, and the supply base. The party will then

Coal Commission Urges Supervision of the Industry by Commerce Commission

Final Report Summarizes Previous Reports—Recommends Action by
Government, the Industry, and the Public

The United States Coal Commission selected by the President on October 10, 1922, has given nearly a year to collecting facts concerning the industry and to the study of the data so gathered. During that time it has submitted numerous reports dealing with various phases of the industry and now it has concluded its work by submitting a final report to the President and Congress. This report is abstracted below.

Both to protect the public and to promote the normal development of coal mining as one of the great basic industries of the country, the Coal Commission in its final report recommends

Fire Sweeps Thirty-Seven Blocks in Berkeley, Calif.

Special Correspondence

Thirty-seven city blocks in the residential district of Berkeley and joining the University of California campus were swept clean by fire on Sept. 18 when a strong wind drove a brush fire from the hills into the city. Averaging the value of the 640 buildings destroyed at \$7,000 each the total structural loss is estimated at \$4,500,000. The district burned was exclusively residential containing practically no fireproof construction. The destruction was complete, only brick chimneys were left standing in the path half a mile wide along which the fire advanced for about three-quarters of a mile. There were no fatalities.

The striking feature of the fire was the rapidity of its advance due to a strong wind which carried burning embers to dry shingle roofs, repeatedly causing roofs in an entire block to blaze up almost simultaneously. Firefighting equipment was sent in from neighboring cities and dynamite was used to raze buildings in the path of the flames, but the fire advanced steadily until the wind abated. There was ample water in the reservoir but due to the failure in recent years to meet needed increases in the distribution system the amount of water delivered was inadequate and at some points the supply failed altogether.

Conclusions are that fire breaks must be provided to keep brush fires from residential districts and that a fire advancing along a wide front with a strong wind in such a district is at best extremely difficult to check, and without adequate water will be beyond control.

be shown around the harbor on government and harbor tugs, visiting the Portsmouth Navy Yard, the naval hospital, and the coal piers of the Norfolk and Virginian Rys. The next stop will be at Old Point Comfort. From there Yorktown will be visited and then the party will pass up Chesapeake Bay and the Potomac River to Washington, D. C. One of the most interesting of the trips in Washington will be a visit to the Arlington Experiment Station, U. S. Bureau of Public Roads.

the use of the powers of the federal government over interstate commerce by the creation of a division of the Interstate Commerce Commission to exercise the necessary administrative and quasi-judicial functions required for the coal industry. "The function of the government is that of supervision, with substantial powers of regulation. The same principle has been applied for a longer time to the railroads and this may be regarded as the characteristic American and constitutional method of dealing with such a national problem as is now presented in the coal industry. The commission has aimed to make such proposal as will increase rather than decrease the sense of responsibility within the industry. A legitimate pride in workmanship, in fair practice, in operating and commercial enterprise will be developed not by taking over from an industry its own natural functions and placing them in the hands of the government, but by such measures as will insure public knowledge and will create public confidence that abuses are in a fair way to be removed, and that service is constantly improving. This means drastic regulation when necessary as a last resort for those who will not voluntarily give the service on reasonable terms; but it means also a reasonable attitude on the part of the government and the public toward investors who risk their capital either in operating or in marketing, and toward miners who risk their lives in a laborious and hazardous occupation."

The commission goes on to say that it realizes that it is passing upon an economic fact and not upon a law, and that the government can act only through administrative agencies, that if anything is to be done an effective agency with sufficient funds, experience, and powers at its disposal must be charged with the direct responsibility for such regulation and supervision. It believes that the logical and appropriate agency to exercise the necessary administrative and quasi-judicial functions already exists in the Interstate Commerce Commission. "The regulation of commerce in coal involves the right to know the cost of its production, whether the investment on which a return is claimed is fairly estimated or inflated, and what profits are made by owners, operators, and the dealer, and what are the earnings and working conditions of the miners."

Under the proposed arrangement the whole responsibility for the administrative correction of abuses, the regulative function, will be placed with the Interstate Commerce Commission and the fact finding and interpretation of the facts might be divided between the Geological Survey and the Bureau of Mines.

The first step toward the protection of public interest in the mining and marketing of coal will be the publication of facts concerning the industry so that the people will be able to exercise wisely the power of government over this type of private business. Both the government and the leaders

if the coal industry will then be responsible if the public has no proper conception of what coal means to the country, what conditions have to be met in the mining and distribution of coal, what economies can be effected, and what advance is needed for bettering the working conditions of the miners. Such publicity will make it possible for the consumer to judge whether a fair price is being charged for his coal, and to form a judgment as to the equities of disputes between operators and miners over the renewal of wage agreements.

Use of Federal Powers.—But the government, according to the commission, to fulfill its obligations to the people must go beyond continuous fact finding and publicity. It must regulate and supervise. "In the anthracite industry, the fundamental evil is monopoly—the treatment of limited natural resources as if they were like other private properties." This industry has been stabilized but at a high cost to the consumer and with such inequalities in the wages of the miners as to require a thorough revision of the wage scale. The special report on anthracite disclosed these conditions as well as excessive royalties and differential profits. These disclosures demonstrate the necessity of "limiting the margins to a reasonable return on legitimate investment and the elimination of monopoly profits."

"One remedy, short of price fixing or public ownership, remains in the hands of the government for the protection of the public interest. This is the levy of a graded tax on royalties and differential profits. This would not lower the price of coal, but would secure a public revenue without increasing the price of coal. The present sales tax imposed by the State of Pennsylvania on anthracite gives no such protection, . . . since it is a percentage on the f.o.b. mine price . . . and is therefore passed on to the consumer in the form of still higher prices. An excess profit tax, . . . under these monopolistic conditions, would not be added to the price of coal . . . as it would only fall on those who have differential advantages."

"The main remedy, however, against extortionate prices lies in the consumer himself. There are substitutes for hard coal and a readiness to resort to them is the ultimate and effective defense against an unreasonable price."

In the mining and marketing of soft coal which "from the point of view of national economic life is the more important industry has the fundamental evils of overdevelopment, and irregularity of operation, and consequent enforced idleness of the miner and the invested capital. This problem can be solved by the federal government . . . through the granting or withholding of transportation service and the consequent establishment of an equilibrium between demand and output."

"The most convenient and practicable of the various possible methods of exercising the right of control over the interstate commerce in coal would appear to be the licensing of all who desire to ship coal from one state to another or to buy and sell in interstate commerce, whether as operators, wholesalers, or jobbers. Reasonable conditions . . . would naturally be attached

to the granting of the license and violation of them would be cause for suspension or revoking the license."

General Recommendations.—The commission's findings of fact and its conclusions based thereon have been given in a number of preliminary reports dealing with both the anthracite and the bituminous industry, and appendices to these reports and on other subjects resulting from the commission's studies will be transmitted to Congress at a later date. This final report summarizes the recommendations already made and concludes with three general recommendations made to the parties in interest, namely, "the general public in its governing capacity, whether represented by Congress or other legislative bodies; second, the coal industry itself—operators, mine workers, and retail and wholesale dealers; and, third, the great body of coal consumers—railroads, public utilities, and the millions of citizens who buy coal. These general recommendations are (1) governmental actions; (2) actions by the industry, and (3) actions by the consumer."

Governmental Actions.—This first recommendation of the coal commission is that Congress make definite provisions on a permanent basis for continuing the collection of coal facts by the Interstate Commerce Commission, as outlined above, and the determinations by Congress under what conditions the products of these mines may pass in interstate commerce. The river movement of coal, considerable at one time, but since discouraged by artificial rail rates, would help to get more coal to market with less coal cars. "Economy in the use of transportation also demands that the long haul of coal be no longer encouraged by favoring rates established without adequate regard to the cost of the transportation service rendered." In order to furnish "an economic incentive for regular, off-season purchase and storage of bituminous coal, thus increasing the length of the average working year for both miner and mine and so reducing the cost of production, the controlling influence should be given to the commercial factor in the distribution of railroad cars to coal mines in times of transportation shortage. By this change in practice, first consideration would be given to the commercial ability of the producer to sell coal rather than to mere ability to produce and load it into railroad cars."

"As administrator of the public estate which includes 50,000,000 acres of coal land . . . the federal government has a direct responsibility in restraining overdevelopment . . . and should amend the leasing law to give the Secretary of the Interior full discretion to make his approval of the opening of a new coal mine . . . contingent on the showing before the Interstate Commerce Commission that such a mine would serve the public and not involve a needless investment and excessive cost of operation."

The commission also recommends that Congress designate an agency to unite with the industry in continuing studies of unemployment, of the rate structure, and serving as a medium of publicity for all basic facts on which industrial relations depend. Such an agency would best be prepared to make special compulsory investigations when-

ever the prospect of failure to renew an agreement is imminent. In all the investigative work relating to mining it recommends that the federal government should continue to co-operate with the state governments in inspection, revision of mining codes, supervision of compensation insurance, and in safety education, and should see that state inspection is freed from politics, that some state codes are revised, and that the regulations of the Bureau of Mines are rigidly enforced.

"The consolidation, grouping or pooling of bituminous mining operations should be not only permitted but encouraged, with a view to securing more steady production, less speculative prices, a wider use of long-term contracts with consumers, better living conditions, more regular employment, and lower cost. The existing legal barriers to such an economic arrangement should be removed, retaining, however, the necessary protection to the public interests, by requiring supervision of the financial structure of the consolidation as is prescribed in the Transportation Act for railroad consolidation."

"There is neither constitutional nor economic warrant for the federal government undertaking the distribution of coal in the several communities of the country. . . . Therefore, it is the function of each community by licensing retail coal dealers, by organizing co-operative associations, by establishing municipal fuel yards, . . . to take the necessary steps that after the coal reaches the railroad siding the distribution thereof is made to the consumer upon a fair and equitable profit to the distributing agency whatever it may be."

Action by the Industry.—"The commission realizes that the largest opportunity and the largest responsibility for putting the coal industry in order lies with the industry itself. The coal industry reveals . . . two distinct and contrasting tendencies in management. There is one that is animated by a purely inquisitive and exploiting spirit that has no other apparent end in view than to make money for the owners. Quick to make most of any panic among buyers, of any opportunity, to pyramid sales, to sell adulterated coal or to cut the wages of miners. This type of operator and dealer resents public interference or public knowledge of his business. He is rightly called a profiteer. . . . But besides profiteering there is also in the coal industry . . . a less conspicuous but equally unjustifiable element in the cost to the consumer." It is "a substantial part of the amount paid in royalties and in excess profits to owners of wealth who perform therefore no useful social service and who take no part in production. . . . There is no way in which this first deduction from the value of the product can be forcibly prevented, as far as the commission is aware, except through government ownership, which we believe to be both undesirable and impracticable, or by taxation on the excess profits and royalties, which we recommend."

The second class of operators and owners are those that are commencing "to realize their duty as citizens and who by their enlightened self-interest are establishing a spirit of co-operation that will promote the prosperity of the industry. They aim to pay fair wages.

to remove the cause for the sullen hostility which prevails to an astonishing extent among workers . . . to make mining a safer occupation even if this means lowering down production, to sell at a reasonable price that will bring a fair return to the investors with steady operation of the mines, to establish a reputation for clean and well prepared fuel, to standardize fair practices in contracts between sellers and buyers, to lay out and develop the mines in such a way as to conserve and economize the coal and to bring it to the market at the least expense, and to come through clean as an industry capable of solving its own problems, with a minimum of governmental supervision—all this is already clearly in the minds of many operators, miners, and dealers." The commission has greater confidence in such internal organization and such educational work as will promote these remedies than in any which is within the power of the Congress or legislatures to apply.

Opportunity for co-operative effort is in bettering conditions outside of the mines by providing better sanitary arrangements, by better roads and streets and schools, by improvements in the food supply, and in the facilities for healthy outdoor recreation. In their labor relations, common interest should lead both operators and miners to study the problem of unemployment and to seek to stabilize the industry. Joint committees should study the whole rate structure and its relation to the different jobs in the mines, perfect the machinery for settling disputes through conciliation or voluntary arbitration, and in the non-union field see that adequate check is kept on the right of discharge. "The operators need more effective organizations for labor relations and we recommend district and national labor commissioners, men of the highest type, who can work out a national labor policy. If the Sherman Anti-Trust law prevents the operators from combining together for the purpose of collective bargaining with the miners, which the commission does not believe is the case, then Congress should exempt them from the operation of the law for that purpose.

DISCUSSION OF CHECKOFF

"There are valid objections to the checkoff, especially in the collection of fines and assessments, and it has also injurious effects upon the union in divorcing the problem of income from the winning of membership, and in the resulting lack of closeness of contact and of educational service and control by the higher officers to the lower officers, and to the rank-and-file members of the unions; yet the checkoff is not vital enough to justify a suspension of operations, whether the union is seeking to extend its use or the operator seeking to throw it out.

"The history of the past 30 years affords conclusive evidence that the United Mine Workers of America has been the potent agency in the betterment of the miners' working and living conditions, and it is necessary today for the protection of standards that have been obtained. However, unless the union accepts in practice the principle that the public interest is superior to that of any monopolistic group, whether employers or employees, and gives satisfactory guarantees of a fair and orderly adjustment of controversies

U. S. Sells Gorgas Steam Plant to Alabama Power Company

Secretary of War Weeks on Sept. 24 sold the Gorgas steam power plant on the Warrior River to the Alabama Power Co. for \$3,172,487.25. This plant was built during the war by the government on land belonging to the power company, with a contract provision that the company could purchase it at a fair valuation. It was built as an addition to the Muscle Shoals plant to which it was connected by a transmission line. The total cost to the government was \$4,750,000. Much interest has been attached to the plant because Henry Ford in his offer for the Muscle Shoals development has contended that he must have the Gorgas plant to make the development complete.

in other ways than by the exercise of economic force, the public will not view with sympathy the efforts of the union to extend itself over the whole field of the industry."

Action by the Consumer—The commission believes that part of the cure for the existing bad conditions is in the hands of the consumer, and that much can be done by preventing peak demands through systematic storage of coal along the lines indicated by the Federated Engineering Societies. It also believes that a further remedy lies in the purchase of coal by contracts which are more than mere options, and in the proper use of coal through careful studies as to the best grade of coal to suit the needs of both large and small consumers.

An executive order of the President has been issued which transfers the records and property of the commission to the Department of the Interior, and designates the Director of the Geological Survey to perform the administration duties incident to closing the work of the commission.

Drinker Becomes Chief Engineer of New York Port Authority

The chairman of the Port of New York Authority has announced the promotion of William W. Drinker to be chief engineer to fill the vacancy created by the death of B. F. Cresson, Jr., last January. Mr. Drinker began active engineering work as a resident engineer and inspector on the Lackawanna R.R., 1893-1898. From 1898 to 1900 he was construction engineer for the Delaware & Hudson Company's coal department. In 1900 he returned to the Lackawanna R.R. as an assistant engineer on yard and terminal work. In 1902 he went to the Erie R.R. as an assistant engineer on yard and harbor terminal work, which position he held until he was made assistant chief engineer of the same road in 1913. When the New York-New Jersey Port and Harbor Development Commission was created in 1918 he was made terminal engineer, remaining with that commission until its work was taken over by the present port authority in 1921. Since that date he has been terminal engineer and latterly acting chief engineer of the port authority.

Rigid Structures Survive Japan's Earthquake

(Concluded from p. 527)

IN TOKYO

The Imperial Hotel of reinforced concrete and fireproof construction withstood both the quake and the fire and stands in good condition structurally.

The Marunouchi Building, of steel-frame and brick construction eight stories high, stood well with the loss of a few bricks. The Mitsukoshi Building, six stories, carrying a tower of three stories, of reinforced concrete, stood well with the possible and doubtful exception of one story, as reported by a very excited Japanese woman who was in the building at the time. The Marut Building of reinforced concrete is reported standing but cracked.

The Shimbashi Railway Station, with steel skeleton and brick walls, is intact.

The Nuzin Building of reinforced concrete and steel is reported standing but probably cracked.

The three story Healing Building of wood and brick was entirely wrecked while a reinforced-concrete building across the street was not damaged. A one-story wooden building next to this reinforced-concrete building was not damaged, so the fact that a building in Tokyo was not damaged is not necessarily any indication of earthquake-resisting qualities but the fact that the only buildings to stand in Yokohama were of steel or reinforced concrete is conclusive proof that these materials are the best in use today for such emergencies and that they have excellent quake-resisting qualities.

Two reinforced-concrete bridges about 100 ft. in length of three spans each at Saguragicho withstood the quake. Many steel girder bridges of one span between Tokyo and Yokohama were shaken from their foundations and dropped into the river, always without failure of the steel. Many very heavily constructed wooden temples were totally demolished.

Railroad tracks were shifted from side to side several feet in waves of perhaps 300-ft. lengths.

The water system in Yokohama was destroyed by the first shocks causing geysers a foot in diameter, in places. The water system in Tokyo, while damaged, was still available for fighting fires.

Japan has no extensive municipal sewerage systems.

The electric wires in Yokohama were completely thrown to the ground, electrifying great numbers of people.

EARTH CRACKS OPEN

When asked as to the depth of the earthquake crevasses, the engineer could not say as he did not take time to examine but rather ran and jumped as occasion required to escape. In places, he said, he saw the earth on one side of a crack move in one direction while the earth on the other side moved in the opposite direction parallel to the other movement and to the fissure.

Seismograph records indicate a maximum movement of the earth of about 3 in. vertically and 7 in. horizontally. Such records have little value in view of actual photographs showing uplifts and depressions of many feet—5 ft. certainly, perhaps 10—and horizontal movements of 2 to 4 ft. or more.

American Construction Council Has Annual Meeting

At its annual meeting in New York City on Sept. 21 the American Construction Council paved the way for an increased activity in the coming year on certain subjects which have been selected as outstanding in the building industry. Work is to be carried on under the direction of new committees, which are now in process of selection. The problems, as stated by the Executive Committee of the council are as follows:

"The promotion of and co-operation with local building congresses, a national survey of apprenticeship needs and conditions of labor supply, promotion of the stability of employment and reduction of unemployment, comprehensive steps toward the determination of the causes and the elimination of waste in all its phases throughout the industry, a general educational program as to the problems of the industry and its development, and the promotion of the concept of construction activities as a great American industry." The public meetings were confined to general discussion of these problems.

Three resolutions were adopted. In the first it was stated that while the collection and distribution of statistics to serve as a barometer of building were most necessary, the council will defer action toward such an effort. The second resolution favors co-operation of all members of the council with all the agencies now promoting apprentice training, and the third authorizes such sums as may be available up to \$25,000 "to be used in the promotion of building congresses in various centers."

D. Knickerbacker Boyd, of Philadelphia, has been made executive vice-president of the council and Dwight L. Hoopingarner, executive secretary, with offices at 28 West 44th St., New York City.

Contract Awarded for Delaware River Bridge Cables

At a meeting of the Delaware River Bridge Joint Commission on Sept. 22, award of Delaware River Bridge Contract No. 8, for construction of the two main cables, was made to the Keystone State Construction Co. of Philadelphia. The award was made upon the basis of bids opened Sept. 19, as follows:

Item	Classification	Estimated Quantities for Comparison	Keystone State Construction Co.		Fred'k Snare Corp' New York	
			Unit	Amount	Unit	Amount
1	Wire cables.....	13,500,000 lb.	\$0 18	\$2,430,000	\$0 18 1/2	\$2,484,000
2	Suspender ropes.....	50,000 ft.	1 60	80,000	1 90	95,000
3	Steel castings.....	180,000 lb.	0 15	27,000	0 20	36,000
4	High tensile bolts.....	6,000 lb.	0 15	900	0 20	1,200
5	Structural-steel plates.....	30,000 lb.	0 20	6,000	0 12	3,600
6	Cast-iron separators.....	30,000 lb.	0 10	3,000	0 15	4,500
Total bid.....				\$2,546,900		\$2,624,300

These are the second bids submitted for the construction of the cables, the first opening having been held on Aug. 15, 1923, and bids rejected because they were in excess of the funds available for the work, as noted in *Engineering News-Record* of Aug. 23, p. 322. This contract is the fourth Delaware River bridge contract secured by the Keystone State Company. They constructed the main piers under Contract 2, and they are building the two anchorages, Contracts 4 and 5. The work under Contract 8 will require in the neighborhood of 18 months.

Officials Deprecate Report That Birdseye Party Is Lost

Publication in the daily press of a sensational article suggesting that C. H. Birdseye, the chief topographer of the United States Geological Survey, and his party have been lost while engaged in a survey of the Colorado River, is deprecated by the Director of that Bureau. The article apparently is based entirely on the discovery of wreckage of a Survey boat. Survey officials are confident that this is the boat lost recently by the Water Resources branch, when it was carried from its moorings by high water. Col. Birdseye and the members of his party are thoroughly familiar with the vagaries of the Colorado River and there is no evidence that they have been in any danger.

Kansas Society Starts a "Journal"

The monthly news-letter which the Kansas Engineering Society has been publishing for the past few months is now styled the "Kansas Engineering Journal" and its August number appeared under the new name. It is a 16-page publication 9 x 11 1/2 in., with local news and some of the papers read at the annual convention of 1922. The journal, which supersedes the former annual volume of "Proceedings," is published at Wichita, Kan., under the direction of P. L. Brockway, president, and C. V. Waddington, secretary, of the Kansas Engineering Society.

Contract Awarded for Driving Moffat Tunnel

On Sept. 18 the Moffat Tunnel Commission entered into a contract with Hitchcock & Tinkler, of New York and San Francisco, to construct the Moffat tunnel on the line of the Denver and Salt Lake R.R. The contract price for doing the work is \$5,250,000, and the contractors are to do the work for a fixed fee of \$140,000.

The contract stipulates that the work shall be completed in 46 months, that should the cost be less the saving shall be equally divided between contractors and commission, that should the 46-month limit be exceeded the contractors shall be penalized \$1,000 per

day and that should the work be done in less time than is stipulated, the contractors shall receive a bonus of the same amount.

Hitchcock & Tinkler are well known in the west for tunnel work, that firm having but recently completed the 18-mile Hetch-Hetchy tunnel for San Francisco's water supply. The firm also built 16 miles of the Denver and Salt Lake road, including 15 tunnels, and some 500 miles of railroad in the Southwest for the El Paso and Southwestern Ry.

Arizona Presents State Plan To Develop Colorado Power

Washington Correspondence

A plan for the development of the power resources in the Arizona sector of the Colorado River by the state was laid before the Federal Power Commission Monday. Arizona was represented by Governor Hunt and a committee of nine. State Senator Elliott, acting as spokesman for the committee, denounced the Colorado River compact as unfair to Arizona. He said Arizona was asked to agree but got nothing in return. He intimated that federal officials had attempted to coerce Arizona into signing. Arizona is not objecting to granting the Girard license and the development of the power at Diamond Creek by the copper companies, it was explained. The state feels that it will be able to take over those developments when it is prepared to proceed with its comprehensive development of the river's power resources. The upstream states are scheduled to reply to the Arizona contention at an early date.

Railway Roadmasters Hold Meeting at Chicago

Few and short reports, active discussions and a large attendance marked the forty-first annual convention of the Roadmasters and Maintenance-of-Way Association, held at Chicago on Sept. 18 to 20.

In a report on "Track Maintenance in Large Yards," R. W. E. Bowler, division engineer, Pennsylvania R.R., pointed out that with modern heavy cars and heavy switch engines it is not economical to use light or worn rails or to neglect maintenance work. Somewhat the same view was taken by W. F. Muff, roadmaster, A. T. & S. F. Ry., in a report on "Maintenance of Branch Lines." Although traffic may be light as far as number of trains is concerned, the weight of cars is likely to be much the same as on main lines, and even heavy engines may be operated. He considered second-hand 80-lb. rail from main track to be advisable, rather than the 56- to 60-lb. rails sometimes used.

Labor saving devices were reported upon by A. M. Clough, roadmaster, New York Central R.R., who referred to the increased weight of modern track material. Cranes and hoists for handling material, ditchers, ballast cleaners and track shifters represent the larger class of machinery, while for ordinary track work there are numerous electric and pneumatic tools for tamping, drilling, sawing and similar operations. Methods of tie inspection, treatment, distribution and renewal on the Atchison, Topeka & Santa Fe Ry. were reviewed by S. D. Cooper, assistant manager of treating plants, who showed that under these methods the number of ties renewed per mile has been reduced from 336 in 1898 to 158 in 1922. Maintenance of rail joints was the subject of a paper by R. S. Cochran, assistant engineer, A. T. & S. F. Ry. The new president is J. B. Martin, New York Central R.R.; vice-presidents, W. F. Muff, Santa Fe Ry., and G. W. Morrow, New York, New Haven & Hartford R.R.; and Secretary J. P. McAndrews, C. & N. W. Ry., Sterling, Ill. The 1924 convention will be held in New York.

Engineering Societies

Calendar

Annual Meetings

INTERNATIONAL ASSOCIATION OF STREET SANITATION OFFICIALS, Chicago, Ill.; Annual Conference, Chicago, Sept. 27-28, 1923.

AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 8-11.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 17-20.

AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga., Nov. 12-16.

CITY MANAGERS ASSOCIATION, Lawrence, Kansas; Annual Meeting, Washington, D. C., Nov. 13-15.

The Boston Society of Civil Engineers Sept. 19 considered the subject: "Apprenticeship in the Boston Building Trades," with discussion of the recently-adopted system for the enrollment of apprentices by several of the building trades; by William S. Parker on the situation leading up to the system; Major H. S. French, speaking from the employer's standpoint; and James M. Gauld and George Thornton representing the views of the trade unions and employees.

The Colorado Section, American Society of Civil Engineers, were hosts at a banquet given Sept. 13 to Charles F. Loweth, chief engineer of the Chicago, Milwaukee & St. Paul R.R., and president of the Society. More than 100 members of the society were present, the principal speaker being Mr. Loweth. Other out-of-town engineers present were: Leonard Metcalf, of Metcalf and Eddy, Boston; and J. Vipond Davies, and J. Waldo Smith, of New York, and Chief Engineer Keyes of the Moffat Tunnel Commission. John S. Means, president of the Colorado Section, presided.

The Engineering Society of Western Massachusetts held its monthly meeting Sept. 25 at the new power development of the New England Power Co. at Whitingham, Vt., the motor trip starting from Springfield, Mass.

The New York Section of the American Water Works Association will hold its annual meeting Oct. 6 at Watertown, N. Y. Charles R. Bettes is president and Burt B. Hodgman is secretary of the section.

Personal Notes

LEWIS B. SMITH, Rochester, N. Y., has been appointed assistant office engineer of the municipal engineering department of Rochester. Mr. Smith has been in this department since 1919, at which time he was transferred from the water-works bureau. He at one time superintended the construction of the conduit line from Rush to Rochester.

PROF. A. DIEFENDORF has assumed his new duties as assistant professor of civil engineering at Rose Polytechnic Institute, Terre Haute, Ind. The past two years Prof. Diefendorf has taught in the University of Illinois. He is a graduate of Ohio Northern University.

DANIEL B. LUTEN, of Indianapolis, Ind., president of the Luten Engineering Co., has been appointed a member of the Indiana state board for the registration and examination of engineers and land surveyors, succeeding R. L. McCormick, of Terre Haute.

HENRY RIEGER, for several years assistant city engineer of Phoenix, Ariz., has been appointed city engineer of that city.

JOSEPH H. STEPHENS, president of the Merchants National Bank of Sacramento, has been appointed a member of the California State Reclamation Board, succeeding PETER R. GADD, who recently resigned.

CHARLES F. ABBOTT has been selected by the American Institute of Steel Construction to assist LEE H. MILLER, who was made managing director of the organization last January, in the technical work of the institute, which centers around the adoption of a standard specification. Mr. Miller will continue his work of direction from the Cleveland office, as chief engineer of the organization, and Mr. Abbott will direct the affairs of the institute from an office soon to be located in New York City.

GEORGE LAMPING, Seattle, Wash., was elected president of the Pacific Coast Association of Port Authorities at its annual convention at Seaside, Ore., last week.

WILLIAM H. CARTER, commissioner of public works at Santa Monica, Calif., for the past twelve years, has resigned his unexpired term to accept the position of business manager of the Pacific Palisade Association.

H. E. SPRY, formerly construction engineer with the Genesee Construction Co., Rochester, N. Y., has joined the organization of the Mamer Co. for work in designing and estimating, and is located at Benton Harbor, Mich.

R. L. HOCKETT has been appointed an assistant engineer for the Kansas State Highway Commission, located at Topeka, Kan. He had been supervising plans and surveys for Division 2 of the Missouri State Highway Commission.

JOHN SMALLSHAW, recently made general superintendent of construction for the Smallman-Brice Construction Co., Birmingham, Ala., formerly was superintendent of construction for the Carolina Construction Co.

A. T. FULKERSON is resident engineer on city paving and sewer construction at Newport, Ark., for the Morgan Engineering Co. of Memphis, Tenn. Mr. Fulkerson's previous work was as civil engineer for the Henry W. Horst Co., Rock Island, Ill.

WALTER P. BLOECHER is now engineer in the structural division of Stone & Webster, Inc., in Boston, Mass. He was formerly with Charles T. Main, engineer, and in 1922 joined the Stone & Webster organization in its New York office.

CALVIN CAMPBELL, who is now located at Alamosa, Colo., as superintendent on the construction of railroad shops for Battey & Kipp, Inc., was formerly superintendent of the water-works and assistant city engineer of Cheyenne, Wyo.

DAVID L. YARNELL, since 1916 senior drainage engineer in the U. S. Bureau of Public Roads, in co-operation with the State University of Iowa is conducting hydraulic research investigations on road culverts, at the university hydraulic laboratory. Mr. Yarnell is a graduate of Iowa State College, has conducted special investigations for the Bureau of Public Roads in reclamation of swamp lands and in hydraulic research, and is the author of many reports of the Bureau on these phases of its work.

F. LAVIS, consulting engineer, New York City, sailed Sept. 19 for Bogota, Colombia, to make an examination of certain railroad projects there which the Colombian government has under consideration.

C. MCN. STEEVES has been appointed construction engineer of the New Brunswick Hydro Commission, under the direction of the acting chief engineer, S. R. Weston. Captain Steeves has two degrees in civil engineering from the University of New Brunswick. Since 1906 he has been engaged successively as assistant engineer of the Federal Department of Public Works at St. John, N. B., chief engineer of the Maritime Dredging Co. in dredging work at St. John, in service in France with the Canadian Engineers, and contractor's engineer on the international bridge between Edmunston, N. B., and Madawaska, Me.

Obituary

LOGAN PHILLIPS, a junior engineer attached to the U. S. District Engineer's office in New York City, was instantly killed last week when an iron bracket became dislodged from the cornice of a six story building at 171 Broadway, and fell, hitting Mr. Phillips upon the head. Mr. Phillips had just left the army engineer headquarters after a conference with Col. J. R. Slattery, regarding the dredging of East Chester Creek, work which was to be under Mr. Phillips' direction.

WILLIAM HENRY MERRILL, founder and president of the Underwriters' Laboratories, Inc., died Sept. 16 in Chicago at the age of 55 years. He was graduated from Massachusetts Institute of Technology in 1898 and has been in fire prevention and fire protection work ever since. The work of the laboratories was organized in 1893 by Mr. Merrill. He was a past-president of the National Fire Protection Association.

BENJAMIN T. FENDALL, formerly city engineer of Baltimore and since 1912 secretary of the Maryland Public Service Commission, died Sept. 18 at his home in Baltimore, aged 72 years. He was a native of Virginia and as a young man was connected with the engineering department of the Baltimore & Ohio R.R.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Japan Faces Gigantic Rebuilding Program

Need for American Lumber and Piling
Seen in Reconstruction of Half
Million Edifices Razed by
Earthquake

HOUSING operations as America knows them even in war times, appear insignificant beside the scope of the building operations Japan now faces in reconstructing the great cities of Tokyo and Yokohama, according to Far Eastern Division of the Department of Commerce. The latest reports place the destruction of buildings in the earthquake-devastated areas at 316,000 in Tokyo, or about 71 per cent of the total number in that city, while in Yokohama, out of the 85,000 buildings standing before the disaster of Sept. 1 only 15,000 are left intact. The destruction in the outlying districts may bring the total of buildings destroyed up to the half-million mark, the large majority of which are homes. This number, added to the housing shortage that existed in Japan before the earthquake, will necessitate the construction of dwelling houses on a large scale. Since Japan normally looks to the United States for about 60 per cent of its lumber requirements it is expected that the demand for American lumber during the reconstruction period will be very heavy.

PRICES AND DELIVERIES

The price of Japanese lumber delivered c.i.f. Yokohama or Tokyo has been approximately 20 per cent higher than that of similar qualities of American lumber, and American freight rates have been favorable. The American market also finds itself in a favorable position as regards delivery. It often happens that the Japanese importer can secure delivery from Pacific ports to Yokohama in less time than from Hokkaido, Karafuto, or even from the northern provinces of Japan proper. Japan's preference for American lumber, aside from the price consideration, is due to the fact that our lumber is more nearly like that of Japan proper than the product of any other country from which it draws wood supplies. This similarity of wood makes it possible for Japanese builders to substitute American lumber for Japanese in all building projects. In fact, its use has become so universal that American lumber is now specified in many instances.

KIND OF LUMBER IMPORTED

The principal lumber imports of Japan consist of fir, hemlock, pine and cedar, about half of which is imported in large squares of from 12 to 24 in. and a lesser amount in small squares of 4½ by 4½ in. The large squares are worked up in the local mills and carpenter shops into the different shapes required for general building, while the smaller squares are used as studs for holding up roofs and for supporting

New Tractor Service Schools Are Announced

That the tractor public including owners, operators and others interested may possess more fundamental knowledge regarding caterpillar tractors an extensive educational program is under way, under the auspices of the Holt Manufacturing Co. of Peoria, Ill. and Stockton, Calif.

The "Caterpillar Service School of the North," the first of a series, was held in Wausau, Wis., Aug. 13 to 21, inclusive. Northern distributors for the caterpillars including the E. A. Drott Tractor Co., of Wausau; Lange-Nash Motor and Tractor Co., of Duluth; and the Upper Peninsula Tractor Co., of L'Anse, Mich., co-operated with the Holt company in the conduct of the school.

The school was attended, not only by tractor operators and mechanics, but also by county highway commissioners, superintendents and other officials of various lumber companies throughout that territory. The Wausau school is the forerunner of others to be held this winter at Boston, Richmond, Dallas, Atlanta, Memphis, Minneapolis, Omaha and Peoria.

The operation, adjustment and lubrication of all models of caterpillar tractors were thoroughly explained. Each model was sub-divided into various assemblies, each of which in turn was described in an illustrated lecture following which the students, under the supervision of competent instructors, would totally disassemble these various assemblies and re-assemble them.

The tractor service schools are being conducted by H. H. "Jack" Chambers, director of service for the Holt Manufacturing Co. He is assisted by Herbert S. Hinrichs, Earl J. Howey, Jack Westphal and George W. Rhodes, all men of long years of tractor experience.

beams. The large squares are very popular among builders in Japan and can only be obtained from America.

The only competition confronting the United States in trade in this class of lumber, according to the Department of Commerce, will come from other parts of North America, as the Siberian, Manchurian, Hokkaido, and Saghalien or Karafuto pines and cedars are all of inferior quality and accepted only as substitutes for Japanese and American woods. At the time of the disaster stocks of lumber in Japan were quite large, especially in Kobe, Osaka, and Tokyo. Assuming that all the stocks in Yokohama and Tokyo were destroyed, it is seen that there is still a fairly good supply on hand for immediate emergency purposes. The real demand will come when the permanent construction of the devastated areas commences. The requirements for home building will no doubt be satisfied first and will take the largest share of the lumber imports.

In comparison with our own homes little wood is required for the construc-

Road Show Exhibit Applications Close Oct. 27

Applications for exhibit space at the Good Roads Show to be held in the Coliseum, Chicago, Jan. 14-19, 1924, during the annual convention of the American Road Builders' Association, must be filed at the office of the association, 37 West 39th St., New York, N. Y., on or before Oct. 27. The allotment of space will be made the following week by members of the association's executive committee and the Highway Industries Exhibitors' Association. Demands for space are expected to exceed the amount available. Exhibitors are advised to limit their displays to their latest and most important products.

To fill vacancies on the board of directors of the exhibitors' association created by the resignation of John B. Hittell, C. N. Leet and H. R. Snow the following were elected at a meeting in Chicago Sept. 7: George W. Craig, district engineer, Asphalt Association, Chicago; Lion Gardiner, sales manager, Lakewood Engineering Co., Cleveland; and C. E. Bement, vice-president and general manager, Novo Engine Co., Lansing, Mich.

Construction Equipment Exported

The following exports of American construction equipment were made during July, according to figures collected by the U. S. Department of Commerce:

Seventy-two concrete mixers valued at \$55,041; miscellaneous road making and construction equipment, 890,678 lb., valued at \$150,407; 38 conveyors at \$23,085; 14 power shovels at \$71,186; 715,944 lb. of dredging machinery at \$45,833; 18 cranes at \$88,562; 556 hoists and derricks at \$103,438; 13 water wheels and turbines (under 300 hp.) at \$9,048.

Shipments of roofing material were valued at \$96,341 for asphalt roofing, \$57,769 for asbestos roofing, and \$54,716 for other types of roofing.

Japan was the largest consumer of concrete mixers during July, with 30 valued at \$23,549. One power shovel at \$22,300 was shipped to Honduras and 7 power shovels at \$17,705 to Japan. Roumania bought one shovel at \$9,000.

tion of Japanese dwellings, in which paper, straw, matting and tile (for roofing) play a large part, but during recent years the tendency has been toward a greater use of wood, especially for ceilings and interiors, as the Japanese are very fond of polished wood in its natural colors. In this respect our lumber has lent itself very admirably owing to its superior quality.

Piling will be required in large numbers, the Department of Commerce states, for reconstructing the destroyed docks and waterside warehouses and sheds in Yokohama and Tokyo, as well as for building subfoundations for industrial buildings, bridges, and construction work in general. The city of Tokyo for some time has contemplated the widening and straightening of its narrow, crooked streets, and many have already been designated for this improvement. This plan will no doubt be carried out in the reconstruction program and the widening of the streets will require enormous quantities of paving blocks. Douglas fir has been used in Tokyo's paving program.

Paving Contractors Endorse 13-E Mixer

A. G. C. Vote of 2 to 1 Endorses Utility of 3-Sack Capacity for Medium-Sized Machine—Reasons for Preference Stated

BY A VOTE of 2 to 1, the 13-E or 3-sack paving mixer has been designated by paving companies of the Associated General Contractors as the proper size of machine to supply the requirements of a middle-sized paver. On account of a difference of opinion among manufacturers expressed at the meeting of the Joint Committee on Construction Equipment, in Chicago, July 30, this matter was referred to the Associated General Contractors for determination by referendum to members interested in paving work. Certain manufacturers favored the 12-E or 2-sack machine, while certain others favored the 3-sack type.

The opinion of paving companies concerning this matter is indicated by the replies received to the following questions:

(1) Exclusive of type consideration, which size of paver is preferable for work requiring a medium-sized machine? Result: 94 in favor of the 3-sack and 49 in favor of the 2-sack.

(2) If the 3-sack machine sells at a price of \$1,500, or less, above the 2-bag, would the price be the determining factor to any great number of construction companies? Result: 49 Yes, and 93 No.

(3) If the 3-sack machine is in your judgment more suitable, should the advantage of capacity be sacrificed to the production of a machine at a relatively lower price? Result: 43 Yes, 96 No.

(4) Is it advisable to have a paver between the 7-E and 21-E? Result: 94 Yes, 49 No.

REASONS FOR PREFERENCE

Reasons assigned for voting in favor of the 3-sack machine are as follows:

Samuel Gamble Co., Carnegie, Pa.—"As the paver in question would be used on city streets, car lines, alleys, and other limited paving jobs where material would be handled almost entirely by hand, we believe that the 3-sack mixer would be preferred by the majority of road and street contractors. It would also be the most practical size for retaining walls, culverts, small bridges usually found in connection with road and street work. The question of price we believe in the past has been too large a factor and if the equipment manufacturers will concentrate on a limited number of sizes, high quality, one hundred per cent service, and sell the machine best required to perform the work which the contractor has to do, the question of price will take care of itself."

Winston & Co., New York—"The specifications of a number of state highway departments now provide that no mixer of less than 3 bag capacity can be used in the laying of concrete surface. It is our opinion that the 3 bag paver will meet the requirements for a small-sized unit on city streets cut by car lines, alleys, etc., and at the same time give the contractor a unit of greater changeability and marketability than the 2-sack paver. This is due to the fact that it will also be suitable for use on highway paving work in emergency, or under particular circum-

stances which might make a temporary use for such purposes desirable."

Bent Bros., Los Angeles, Calif.—"We like the large paver because it is not likely to be overworked as much as the smaller one. The vital parts will stand up better under the requirements. This condition does not, however, develop while the machines are new."

As the referendum on the middle-sized paver was sent to all members of the Executive and Advisory Boards and

Next Week

An article discussing some of the problems involved in selling building materials will offer to the purchasers of supplies—contractors, engineers and architects—the point of view of a manufacturer. An understanding of the practices of both maker and user of equipment and materials should be mutually helpful—

Editor

Presidents' Council of the Associated General Contractors, a number of ballots were received from contractors not engaged in paving work. Upon request of the manufacturers ballots from those not so engaged were not included in the tabulation of results unless it was specifically stated that they had consulted paving companies and ascertained their opinion. Most of the companies not engaged in paving work did not submit their vote on the grounds that they believed the matter should be determined on a vote of paving companies only.

Track Exhibits at Roadmasters' Convention, Chicago

Exhibits of railway track material and appliances at the Chicago convention of the Roadmasters and Maintenance-of-Way Association, Sept. 18 to 20, were numerous and varied but included few novelties. Labor-saving devices were not much in evidence, in spite of the marked development along this line in railway maintenance work.

Various makes of motor section cars were exhibited. Nearly all railways now recognize the advantages of these cars as compared with hand cars. Ballast-tamping machines included the Jackson electric tamper of the Electric Tamper & Equipment Co., Chicago, and the pneumatic tamper of the Ingersoll-Rand Co., New York. Ditching cranes, spreader cars and weed-killing cars were represented by views and moving pictures, since the exhibits were arranged on a hotel balcony and there was no opportunity to place large machinery.

One novel device was the Mack switch protector, by J. R. Fleming & Sons Co., Scranton, Pa. This consists of a tapered block bolted inside the rail just ahead of the switch, so that wheels with flanges hugging the rail head are prevented from striking the switch point.

A large part of the exhibit consisted of hand tools and the smaller class of track material, such as tie plates, nutlocks, bolts and rail anchors, together with some derricks, switch and frog details and wire fencing. There were also torches for clearing ice and snow from switches. The exhibit, arranged by the Track Supply Association, comprised about sixty exhibitors.

Business Notes

E. L. SPARKS, for the past five years New England sales manager for the Erie Steam Shovel Co., with headquarters in Boston, has resigned to open an advertising service agency in New York next month, specializing in machinery and building material accounts. He served for 4 years as copywriter in the advertising service department of the McGraw-Hill Co., Inc., and the McGraw Publishing Co., and prior to that was engineer in charge of various construction projects.

TRUSCON STEEL Co., Detroit, announces that after Oct. 1 its Michigan office will be located in the company's new building at 615 Wayne St., Detroit, occupying the entire second floor. The office includes a service organization and engineering department, equipped to furnish information, estimates and details on all the company's products, including reinforcing steel, metal laths, steel windows and joists, highway reinforcements, standard buildings, inserts and pressed steel parts.

LINK-BELT Co., Chicago, which for some years has maintained sales and distributing offices in San Francisco, Los Angeles, Portland and Seattle, has just acquired the business and manufacturing facilities of the Meese & Gottfried Co., which for many years has manufactured transmission and conveying machinery on the Pacific Coast. It is the intent of the new owners to increase facilities, enlarge stocks and improve methods of distribution so that the demands of customers can be met promptly and completely.

JOE GLOZIER, Birmingham Slag Co., with offices in the Walton Building, Atlanta, Ga., has been appointed chairman of the Exhibit Committee which will have charge of the display of equipment and materials at the annual convention in Atlanta, Nov. 12-16, of the American Society for Municipal Improvements. Convention headquarters and the exhibit will be at the Ansley Hotel.

BURTON-TOWNSEND Co., Zanesville, Ohio, manufacturer of paving block and building brick, announces the appointment of Arthur M. Crumrine and Samuel A. Kinneer as receivers for the company. Creditors are requested to file proof of claims against the firm with statement of account in detail.

ALBERT S. BOISFONTAINE, who has been assistant to the manager of the Southern Pine Association since last June, has been appointed assistant secretary. He has been with the association, serving in a number of capacities, since 1917.

VALLEY ROLLING MILLS, INC., Elmira, N. Y., recently incorporated under the laws of the State of New York to take over a complete merchant bar and light structural shape mill originally built by the Quirk interests, will begin rolling at once. Marcel K. Sessler of New York enters the organization as vice-president and treasurer, and will be actively associated on the business side, with E. F. Quirk and J. S. Quirk, who are experienced and practical mill

men and will be in charge of the production end of the business. The general negotiations and this consolidation were effected through the Engineering Business Exchange, New York, of which Charles Whiting Baker, formerly editor of *Engineering News-Record*, is director.

Equipment and Materials

Self-Anchoring Stump Puller

A machine for pulling stumps, with a self-anchoring device which makes it unnecessary to tie the equipment to other trees or stumps, has been developed by Monarch Tractors, Inc., Watertown, Wis. The puller is mounted on a three-wheel chassis with a small diameter castor wheel at the front end which permits short turns. Through the two rear wheels passes a large diameter axle which supports a heavy pivoted steel channel frame, the rear end of which carries the anchoring device consisting of a sharp blade. This anchoring blade is forced into the ground as there develops a pull on the machine, holding the latter in place. To counter-balance the heaviest pull weights in addition to that of the machine itself are hung from a boom held in position by guy wires attached to the frame. The boom serves also as a tongue when using horses to move the machine.

The power plant consists of a Ford motor driving a cable drum 12 in. in diameter and 10 in. wide, holding 50 ft. of cable. The motor is fitted with a special water circulating pump. The equipment weighs 5,000 lb., its length is 16 ft., width 6 ft., and height 4 ft. 3 in.

Monarch Self-Anchoring Stump Puller

With this machine a direct cable pull of 50,000 lb. is secured, or 100,000 lb. with a single block. Field experience by the manufacturer indicates that a crew of four men is required to keep the puller working to capacity. They are distributed as follows: One operator, two men handling cables; one man on tractor or team. It is asserted that half an acre of stump land may be cleared at one setting of the machine. The engine has two speeds forward and one reverse so that the slack in the cables can quickly be taken up with the high speed and the stump pulling operation performed in low gear. For pulling stumps not close to the machine several 50-ft. lengths of cable with open and closed rings are used.

Crawler Tractor Makes Another Long Journey

Another long-distance trip has been undertaken by the Monarch crawler tractor which last year completed a journey of 1,513 miles from Watertown, Wis., to New Orleans, starting Oct. 8 and finishing Dec. 11, 1922, a total traveling time of 339½ hr. The same tractor, on Aug. 24, started from the company's plant at Watertown on a 500-mile route to various state fairs in Wisconsin and Illinois and is scheduled to end its trip at Peoria, Sept. 28, where it will be on display at the National Implement and Vehicle Show.

The tractor is pulling a 5,000-lb. two-wheel trailer. On its trip from

at a speed of from 5 to 6 m.p.h. The truck is operated by a 21-cell storage battery and a 36-volt, 35-amp. motor. The truck may be fitted with a crane attachment for special purposes. The height of the loading platform above the floor is 23 in. For handling very heavy and cumbersome materials a low-platform truck has been designed, the platform of which is only 12½ in. from the floor.

Filtration Equipment—PERMUTIT Co., New York, has issued a 23-p. illustrated pamphlet dealing with its vertical and horizontal inclosed steel-shell pressure filters and its open-top gravity filters of wood or concrete. The smaller sizes of pressure filter of the vertical type have shells from 16 to 24 in. in

Watertown to New Orleans the tractor made an average speed of 3.78 miles per hour and covered an average of 26.6 miles per day. Pulling the same trailer as is used on the trip now in progress, the tractor consumed an average of 3.4 qt. of gasoline per mile. The total gasoline consumption on the 1,513-mile trip was 1,290 gal. and the lubricating oil consumed was 30 gal.

Publications from the Construction Industry

Snow Plows—BAKER MANUFACTURING Co., Springfield, Ill., in a 16-p. illustrated catalog, explains the operation of its snow plows designed for mounting on the front end of a truck. The plows are built in two models, one with a straight blade and the other with a V-shaped blade. The straight blade is protected from damage in striking obstacles by the use of safety tipping blades in the form of hinged sections 2 ft. long held in place by compression springs, which allow the sections to tip backward when they strike such an obstruction as a manhole cover. The springs snap the safety blades back into position after the obstruction is passed. The plows are built in lengths of 8 and 10 ft.

Industrial Trucks—CRESCENT TRUCK Co., Lebanon, Pa., has just issued a catalog explaining the design and illustrating the uses of its electric industrial trucks and tractors for handling material in shops and factories, loading cargoes at docks, etc. The company's general utility truck is designed to carry a pay-load of 4,000 lb. in addition to hauling a trailer. A four-wheel steer insures maximum flexibility of operation, allowing the truck to run in narrow aisles, on small elevators, and around pillars and machines in congested factories. This truck operates

diameter, built for a working pressure of 100 lb. per square inch. For larger installations the horizontal type with steel shells of 8 ft. diameter and from 10½ to 25 ft. long are recommended. The text explains, in general terms, the various steps involved in the process of rapid sand filtration.

Water Sterilization—WALLACE & TIERNAN Co., INC., Newark, N. J., has issued two technical publications, each of four pages, on its chlorinators for medium-sized and small water supplies. The text explains the application of this equipment, taking up such matters as amount of chlorine required, pressure against which the chlorine can be applied and diffusion of chlorine in the water. Sketches show typical installations.

Drill Sharpeners—SULLIVAN MACHINERY Co. has just issued a new illustrated bulletin on drill sharpeners for hammer forging drill bits and shanks. These machines are operated by compressed air and the sharpening process is done by hammering, with the steel at relatively low temperatures. In connection with the use of the sharpener an oil furnace, insuring uniform temperatures, is recommended. The sharpeners are made in two sizes, A and B, weighing respectively 4,000 and 1,500 lb.

Clamshell Buckets—BLAW-KNOX Co., Pittsburgh, in a 35-p. illustrated pamphlet, features its single-line clamshell buckets, which utilize the same line for both closing the bucket and for supporting it during opening. A feature of the equipment is the elimination of locks, catches, or other sliding parts. The buckets are built in sizes from ½ to 3 cu.yd. capacity. The text features also the company's single rope cableway in which only one hoisting drum is required for both hoisting and transporting the load along the cable track.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Structural-Steel Sales

The Department of Commerce announces August sales of fabricated structural steel, based on figures received from the principal fabricators of the country. Total sales of 130,568 tons were reported for August by firms with a capacity of 224,305 tons per month.

Tonnage booked each month by 176 identical firms, with a capacity of 230,475 tons per month, is shown below, together with the per cent of shop capacity represented by these bookings. For comparative purposes, the figures are also prorated to obtain an estimated total for the United States on a capacity of 250,000 tons per month.

	Actual Tonnage Booked	Per Cent of Capacity	Computed Total Bookings
1922			
April.....	200,968	87	217,500
May.....	185,065	80	200,000
June.....	168,894	73	182,500
July.....	158,012	69	172,500
August.....	130,568	68	170,000
September.....	146,827	64	160,000
October.....	133,037	58	145,000
November.....	112,367	49	122,500
December.....	136,737	60	150,000
1923			
January.....	173,294	75	187,500
February.....	184,887	80	200,000
March.....	218,400	95	237,500
April.....	186,117	81	202,500
May.....	131,875	57	142,500
June.....	118,063*	51	127,500
July.....	116,774**	51	127,500
August.....	131,770***	56	140,000

* Reported by 174 firms with a capacity of 230,460 tons.

** Reported by 169 firms with a capacity of 229,815 tons.

*** Reported by 158 firms with a capacity of 224,305 tons.

Production of Brick

Regarding domestic production of brick during July the following comment is made by the Common Brick Manufacturers' Association: The brick shipped from plants in July was approximately the same as in the preceding month, and the production of brick showed a slight increase. Ninety-three firms reporting, representing practically every section of the country, show unfilled orders on the books amounting to 342,719,000, brick, which is a little more than 50,000,000 less than was recorded in the Aug. 1 report, which reflected conditions on July 1. This drop is not serious at this season of the year. There is nothing discouraging in the current reports from manufacturers, and out of 76 who indicated future outlook for business, 20 were found in the "good" column, 48 viewed the outlook as "fair" and only 8 say it is "bad." Among the firms reporting only one plant was shut down during the month of July, all others shut down being for less than the full month and that principally for repair. The decrease in unfilled orders is quite evenly distributed over all of the Eastern, Southern and Middle Western territory. In California there is shown an increase in orders on the books and a better condition is reflected in the other coast states and in the Southwest. No price change is recorded.

Wholesale Prices in August

Wholesale prices in August averaged slightly lower than in July according to information gathered in representative markets by the U. S. Department of Labor through the Bureau of Labor

BOOKINGS OF COMMERCIAL STEEL CASTINGS

Month	Total	Per Cent	Railway Specialties	Per Cent	Miscellaneous Castings	Per Cent
1923	Net Tons	Capacity	Net Tons	Capacity	Net Tons	Capacity
January.....	100,605	103 8	47,879	125 0	52,726	90 0
February.....	90,152	93 0	39,845	104 0	50,307	85 8
March.....	143,564	148 2	76,409	199 5	67,155	114 6
April.....	90,968	93 9	39,610	103 4	51,358	87 6
May.....	89,493	92 4	38,788	101 3	50,705	86 5
June.....	84,878	87 6	42,773	111 7	42,105	71 9
July*	52,066	53 7	16,741	43 7	35,325	60 3
August.....	50,515	52 1	18,332	47 9	32,183	54 9

* Two companies with a capacity of 785 tons per month on miscellaneous castings now out of business.

Statistics. The Bureau's index number, which includes 404 commodities or price series weighted in proportion to their relative importance, sank to 150 in August, a drop of 1 point from the figure of the month before.

The largest decrease from the preceding month is shown for the group of fuel and lighting materials, due to further declines in bituminous coal, crude petroleum, and gasoline. The decrease in this group was 2½ per cent. Building materials and housefurnishing goods each declined 2 per cent from the July level.

In the group of farm products increases in corn, rye, wheat, cattle, hogs, eggs, hops, and hay brought the level of prices nearly 3 per cent higher than in July. Foods also averaged higher than in the preceding month. No change in the general price level was reported for cloths and clothing and for metals and metal products.

Of the 404 commodities or series of quotations for which comparable data for July and August were collected, decreases were shown in 137 instances and increases in 110 instances. In 157 instances no change in price was reported.

INDEX NUMBERS OF WHOLESALE PRICES BY GROUPS OF COMMODITIES

Group	(1913 = 100)		1923	
	1922	August	July	August
Farm products.....	131	135	139	142
Foods.....	138	141	142	142
Cloths and clothing.....	181	193	193	193
Fuel and lighting.....	271	183	178	178
Metals and metal products.....	126	145	145	145
Building materials.....	172	172	180	186
Chemicals and drugs.....	122	128	127	127
Housefurnishing goods.....	173	187	183	183
Miscellaneous.....	115	121	120	120
All commodities.....	155	151	150	150

Comparing prices in August with those of a year ago, as measured by changes in the index numbers, it is seen that the general price level has declined 3½ per cent. This is due entirely to the great decreases among fuel and lighting materials, which averaged 34½ per cent less than in August, 1922, at which time a strike was in progress in the coal fields. In all other commodity group prices were higher than in August of last year, ranging from 3 per cent in the case of foods to 15 per cent in the case of metals and metal products.

Bookings of Steel Castings

The Department of Commerce announces August bookings of steel castings, based on reports from principal manufacturers. The bookings in August by companies representing over two-thirds of the commercial-castings capacity of the United States amounted to 50,515 tons, as against 52,066 tons in July. The following table shows the bookings of commercial steel castings for the past eight months by 65 identical companies, with a monthly capac-

ity, of 96,900 tons, of which 38,300 tons are usually devoted to railway specialties and 58,600 tons to miscellaneous castings.

Federal Reserve Statistics on Business Conditions

Production of basic commodities and employment at industrial establishments decreased in July and there was a further decline in wholesale prices, according to the monthly review of business and financial conditions by the Federal Reserve Board. The distribution of goods, as indicated by railroad freight shipments, maintained record totals and the sales of merchandise, though showing the usual seasonal decline to be relatively heavy.

Production in basic industries, according to the index of the Federal Reserve Board, declined 1 per cent in July. New building operations showed more than the usual seasonal decline.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 173 to 185, are the following:

Distributing Station, Middletown, Conn., to R. H. Beattie Constr. Co., Fall River, Mass., \$1,000,000.

Store and Club, San Francisco, Calif., to R. McLeran Co., \$1,000,000.

Home and Infirmary, Wende, N. Y., to H. Shenk, Erie, Pa., \$1,079,000.

Grain Elevator, Oswego, N. Y., to James Stewart Co., New York City, \$1,119,959.

Tunnel, Colorado, to Hitchcock & Tinkler, Denver, \$6,075,000.

Cables, Philadelphia bridge, Keystone State Constr. Co., \$2,546,900.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 173 to 185, are the following:

Hotel, Hot Springs, Ark., Arlington Hotel Co., \$2,225,000.

Apartment, New York, N. Y., Octo Building Corp., \$1,500,000.

Dam, Little Rock, Ark., Arkansas Power Corp., \$1,787,600.

Bridge, Portland, Ore., Comrs. Multnomah Co., \$4,000,000.

Industrial Movements Shown by Commerce Dept. Figures

The Department of Commerce announces the following further figures covering industrial and commercial movements in July:

Total stocks of Lake Superior iron ore at the end of July, amounting to 27,503,000 tons registered an increase of 21 per cent over the inventory of June 30 and may be compared with the holdings on July 31, 1922, of 31,127,000 tons. Imports of iron and steel totaled 113,000 tons as against 72,000 in July, 1922, while the exports of iron and steel amounting to 141,000 tons, may

be compared with 128,000 tons a year ago. Production of sheets by independent steel mills totaled 174,910 tons as against 218,432 tons in June and 179,100 in July, 1922. In terms of per cent to mill capacity the production of sheets amounted to 65 per cent as compared with 80 in June and 73 per cent in July a year ago. Unfilled orders for sheets on July 31 amounted to 404,868 tons as against 503,175 on June 30 and 409,885 on July 31, 1922.

A total of 551,000 employees was on the payrolls of representative New York State factories as compared with 555,000 for June and 490,000 for July, 1922. The index of employment in

Wisconsin factories stood at 128 on July 15, based on the first quarter of 1915 as 100, as compared with 124 on June 15 and 107 on July 15, 1922. The average weekly earnings in New York State were computed at \$27.54 for July as against \$27.85 for June and \$24.77 for July, 1922. For Wisconsin the index of weekly earnings was 209 for July 15 as compared with 226 for June 15 and 186 for July 15, 1922.

Bradstreet's index of wholesale prices at 139 for Aug. 1 may be compared with 142 for July 1, and 131 for Aug. 1, 1922. The index of retail food prices at 147 for July compares with 144 for June and 142 for July, 1922.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual biddings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Sept. 6; the next, on Oct. 4.

Steel Products:	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal

Explanation of Prices—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given; 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. Labor—Concrete laborers' rate, 93¢ c.; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bag; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu.yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5 1/2 x 8 x 11. Prices are all f.o.b. warehouses except C. L. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at \$7.10). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.42; 6-in., \$119.

Changes Since Last Week

Although price irregularities prevail in most commodities at present, with advances very nearly equalling declines, the construction materials market continues to retain that show of stability which has characterized it since the collapse of the "buyers strike" movement. Buyers are still cautious and the increased activity, particularly in iron and steel, that was expected to develop

has not yet completely materialized. Lumber shows increasingly firm tendencies, particularly in the West. Steel, lime, clay products and concreting materials fluctuate little.

Linseed oil, however, continues to decline. Raw oil dropped 2c. in Atlanta and 7c. per gal. in San Francisco during the week.

The iron and steel situation in brief:

Pig-iron stocks accumulating; market weak. Iron and steel scrap adversely affected by weakness in pig iron. Fair volume of new buying in fabricated structural steel, particularly for schools and commercial buildings. Plate demand somewhat slower. Prices holding firmly to the \$2.50 base for plates and shapes; bars, \$2.40 per 100 lb., f.o.b. Pittsburgh.

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTINGE. J. MEHREN, Editor
FRANK C. WIGHT, Managing Editor

Volume 91

NEW YORK, OCTOBER 4, 1923

Number 14

A Useful Service

A MOST necessary service can be rendered by the committee just authorized by the American Society of Civil Engineers to collect data on the behavior of structures in the Japanese earthquake. There were enough modern buildings and other engineering works in the stricken zone to provide information far ahead of anything hitherto available and it is imperative that some orderly and authoritative means be provided to secure this information, digest and analyze it and put it before the profession. This the civil engineers, with the co-operation of other technical societies where they can co-operate, purposes to do. The earthquake zones of the world are comparatively limited but they embrace some of the best and most livable country in the world. Engineers need all the knowledge they can acquire as to the best way of providing the people of these zones with safe and durable structures.

Road Taxes

LESS than 5½c. of the general taxpayer's dollar in 1921 went to highways. During that year about one billion dollars were spent in highway construction and maintenance. These figures are given by John E. Walker, former tax adviser to the United States Treasury. They are of vital significance to highway officials. If reports from Washington forecast accurately the attitude of members of Congress, there will be a strong effort at the coming session to curtail highway appropriations, on the plea of tax reduction. The reaction against highway expenditures, of which *Engineering News-Record* sounded a warning a year ago, has lost none of its impetus in state legislatures. Of the many causes which have led up to this reaction, the greatest is the growing tax burden. How small a portion of this is imposed by highway improvement is not generally realized. This is largely the fault of highway officials. They have not told the people plainly who is paying the bulk of the cost of our improved roads.

Fining Winter Idleness

UNEMPLOYMENT is becoming more generally considered the responsibility of employers. Wisconsin will this winter, according to press dispatchers, discuss in its house of representatives an act providing unemployment insurance. The act has already passed the state senate. Nominally it is an insurance act. Virtually it is a penalty on employers for not eliminating seasonal business. In essence it compels an employer who lays off an employee not because of the employee's fault, to pay him a dollar a day for thirteen weeks. Obviously a big sociological problem is involved. As engineers and contractors, however, the readers of *Engineering News-Record* are chiefly concerned in the effect of the law on seasonal construction. The construction industry has been the most callous of em-

ployers in turning loose its workmen when the busy season of summer had passed. There is no work in winter, it has said, and complacently distributed quitting checks. Getting the industry to think that winter idleness is not a divine ordinance is a hard task. Perhaps a ninety-dollar fine for each employee discharged will bring a more open mind. One is inclined to applaud the experiment.

Farmers Want St. Lawrence Canal

BECAUSE the agitation for the St. Lawrence ship canal is not getting quite as much publicity as it did some years ago it must not be thought that the project is dead. The fact is that conditions of the past few months have only added fuel to the flame of the demand for the waterway. Although wheat constitutes a very small part of the revenue producing crops of the nation and a smaller part of the income of the average farmer it has become the index by which farm prosperity is popularly measured. This is notoriously a bad wheat year and whatever the cause the farmer is pretty well persuaded that high rail rates make up the major part of the trouble. The St. Lawrence shipway would be pre-eminently a wheat-carrying channel. Whether or not it will ever prove profitable for other kinds of freight is something only operation—with its possible relocation of freight routes and development of economical transfer machinery—can tell, but for wheat, which can as readily be brought to lakeside elevators as to any other central distributing point, carrying charges will certainly be lower. That being the case, the farmer sees in the canal the way out of his difficulties. It does not matter whether or not it may be cheaper in the long run for the country to build more railroads or for the railways to reduce rates, this appears to be the easy way out, just as for the last fifty years the waterway has appeared to be the easy way out of all high transportation rate difficulties. So far the waterway has disappointed its advocates. Possibly the St. Lawrence route will, too. But the opponents to the scheme will do well to reckon with the western farmers who are now more than ever in a mood to demand the experiment.

Delusions of Persecution

ONE of the most characteristic exhibitions of the waterway mania is that now being given by the advocates of the New York State Barge Canal. For nearly ten years that much-advertised waterway has been struggling to demonstrate its usefulness. For a large part of that time the state officials in charge have been favorable to water carriage and have done all in their power to promote the use of the canal, but the results have been disappointingly small. There has been some increase in freight carriage, but certainly not enough to prove that the canal will ever be worth

the \$170,000,000 it cost the State of New York. Now the waterway enthusiasts have taken a new tack. Their pet project, they say, is about to become the prey of the politicians of both parties who are engaged in devious effort to scrap the canal entirely or else to convert it into a water-power scheme. The case of the waterway men is pathological. For years they have suffered from delusions of persecution. If either on the Mississippi or the Mohawk they spent nearly the energy to prove by service the economies of water transport as they do in complaining of the unfairness of their competitors, inland waterway freight carriage would today be more than the academic proposition it really is.

Red Tape and a Pontoon Bridge

THE War Department has announced that government material cannot be used without sanction of Congress to build a pontoon bridge across the Connecticut River at Springfield, Mass., to relieve the situation caused by the burning of the North-End bridge on Sept. 8. Evidently there must be some sharp distinction between letting army engineers practice at bridge building by using this sacred government material to build a bridge across the Potomac at some point where it is of no use to anyone and letting them do the same thing across the Connecticut at Springfield, where the bridge would be of great value to a large community. The War Department might well arouse itself to aggressive action in such peace-time emergencies, instead of hiding behind a screen of red tape and precedent. This is an admirable opportunity for the department to go before the people with a much better face when it has to appeal to them for funds to carry on just such work as training men to build pontoon bridges.

Sheets and Pillow Slips

MANY comforts and conveniences have been provided in recent years for common labor in Western construction camps. There is a limit beyond which this cannot be carried, although the demands of labor organizations have sometimes raised the question as to where it could be fixed. Good food, bunk houses with good light and ventilation, handy hot and cold showers, have all been requisites of the successful camp. In recent years contractors found it necessary to keep these facilities up to par to avoid an excessive labor turnover because labor knew where to find camps that *did* provide good food and quarters.

On some jobs now the contractor has gone even further; he provides bed linen. Formerly all laborers carried a blanket roll commonly called a "bundle," or, "turkey," and it was the universal custom for every man to take care of his own bed. When one large camp equipped all bunk houses with sheets and pillow slips the experiment was watched with much interest. Now, a number of large projects with anywhere from one to eight or ten camps provide every man on the job with complete beds, including mattress, blankets, pillows, sheets and pillow slips, the camp organization changing and washing the sheets and inspecting blankets at stated intervals. The Big Creek project of the Southern California Edison Co., operating under this system, does not allow a blanket roll to come into the camp. The Skagit project of the City of Seattle,

from the start of the first camp, has provided bed linen for common labor. More recently even smaller contractors, in order to attract men to short-time jobs, have frequently made it a practice to provide fully equipped bunk houses.

The plan has a two-fold value; it (1) maintains self-respect of the men and makes them feel that they are having the best of care and it (2) improves sanitary conditions by preventing the spread of vermin and disease that would otherwise go from camp to camp in the blanket roll. After a year or two of experience in supplying bed linen and including the maintenance of clean beds as part of the camp organization duties, the consensus of opinion among those who use this plan is that it *pays*. The charge made to the men for linen and blankets—say about \$1 per month—may not cover the actual cost, but any small loss is much more than made up by the improved attitude of labor.

Valuation Principles Still Vague

ON THE correspondence page of this issue Prof. C. C. Williams, of the University of Illinois, makes a plea for the reproduction-cost-new theory of valuation as opposed to the prudent-investment theory which has been tentatively advocated by the minority justices in several of the recent Supreme Court decisions and which, the professor thinks, was defended in an earlier editorial in this journal. That editorial was not intended to support the prudent-investment theory at the expense of the reproduction-cost-new theory, but it was meant to show the complication in trying to set up one base method of valuation.

Unfortunately, it appears that the process of valuation cannot be reduced to any simple formula. It is true that the Supreme Court rulings for many years have leaned toward the reproduction-cost-new method, but they have by no means pronounced it absolute. The cost today to reproduce the property has been advanced as one of the elements—occasionally a governing element—in determination of fair value; but even where it is possible simply to arrive at that cost (which it rarely is) the court has not always accepted it as the final value. Justification for the investment, the degree of use, the market value of the property as expressed in the securities—all elements in the so-called prudent-investment theory—have always entered into the determination of value as reached by the highest court. That court has always recognized, we think, that the public should not be made to pay a toll for the mistakes which public utility promoters have made.

No better example of the fog that surrounds valuation or of the difficulty of arriving at an exact figure in valuation could be found than the report of the Interstate Commerce Commission on the final valuation of the San Pedro, Los Angeles & Salt Lake R.R. just made. The commission in this case gives as \$45,000,000 the final single-sum value of the property for rate-making purposes as of July 1, 1914. This is a majority report concurred in fully by eight of the eleven members and partly by two others, and yet the report itself shows that there were as many methods of arriving at this exact sum as there were members of the commission. The sum of \$45,000,000 does not represent prudent investment. It does not represent reproduction cost new, or stock value, or selling price, or any other one thing. It is merely a figure which ten men are willing to agree

upon as the value in 1914 of a small railroad, that figure to be used as a base for rate making at some date years after 1914, with the method to be followed in bringing the value up to the rate-making date left unsettled. It is, as Commissioner Meyer says, the approximate investment on which those devoting this property to common carrier service were entitled to a fair return in 1914.

While, therefore, engineers will heartily concur in Professor Williams' suggestion that an adherence to one method of valuation would remove much of the foginess which now beclouds the whole subject, there is little chance, it seems to us, that it can be made a simple process. There is a chance as time goes on and the records of public utilities are kept more precisely and the current prices of material and labor are more fully a matter of record, that a fair value will be more readily established than it is now when records are scarce and past unit prices doubtful. In the future, with the reproduction-cost-new theory governing, as it has been in the past, but not absolute, there should be a more close agreement between the public idea of the value of a utility and the idea of the owners themselves.

A Step Ahead in a Major Problem

A MAJOR problem in both local and national transportation is moved appreciably nearer solution by the agreement last week between the railroads and the Port of New York Authority in the matter of the New Jersey marginal railroad. The agreement is important in that it breaks a deadlock which has been hampering the proper delivery of freight into New York—which means that the whole country as well as New York has been hampered—but it is equally important because it marks the acknowledgment by the railroads of the force of public opinion and a definite step ahead in the establishment of the power of the Port of New York Authority.

Heretofore, despite the wording of the treaty which established the authority, there had been some doubt as to how much pressure it could bring to bear in case its powers were in question. Just such a doubt was in the minds of the railroad officials when the hearing on the marginal belt line opened before the Interstate Commerce Commission last spring. But the recent about face of the same officials, representing the most powerful railroads in this country, is ample evidence of how definitely the powers of the port authority were established at that hearing. Such being the case the authority is now in a much better position than ever before to proceed with its "comprehensive plan for the development of the Port of New York."

The marginal belt line in New Jersey, the subject of the recent action, is only a small part of that plan. There are other details that call for immediate action. The chief one is the so-called middle belt line No. 1, a belt line starting from connections with the New Haven and the New York on Long Island and running down to Bay Ridge and across by a tunnel to the New Jersey and thence up to connect with all the trunk lines on that side. The railroad companies have already taken steps toward building this latter section but the connection across the bay to Brooklyn is badly needed to divert the through traffic for New England away from the congested areas along the west shore of the Hudson. The port authority's plan calls for the construction of

this connection as a tunnel under the Upper Bay from Bayonne to Bay Ridge. But under legislative enactment the City of New York is now building a tunnel for similar purposes under the Narrows from Staten Island to Bay Ridge. Obviously both tunnels should not be built, at least not for many years to come, and the railroad connections for the two tunnels can be altered to suit whichever tunnel it is deemed most advisable to construct. Either route can be made to suit the needs of traffic. And as far as immediate needs are concerned the Narrows tunnel has the advantage over the Upper Bay tunnel in that it is only half as long and is already under construction.

Now that the port authority has its feet on solid ground it would seem that it should take some definite action towards completing this major belt line. The conditions are most favorable. The city government is determined that the Narrows tunnel shall be built and it has legislative "mandate" to support its action. But it lacks the one thing needful—money. If it spends the necessary millions on this tunnel it will have little left for other needed utilities such as subways. It is here that the authority can display its usefulness to the city and at the same time perhaps remove much of the antagonism towards it that now exists in the present city administration. It can, under the laws which created it, revise its plan to make the Narrows tunnel a part of that plan, issue bonds to finance its construction, and take over the construction from the city, thereby allowing the city to use its moneys for other purposes.

But before the port authority can take this step the city administration must publicly abandon the idea that the Narrows tunnel can be used as a combined freight and passenger tunnel which will be able to handle the great volume of freight that will be routed through it and at the same time give Staten Island a frequent passenger train service to Manhattan Island. The passenger use of the tunnel has been minimized in the engineering reports but has been played up very strong by the political friends of the city administration, obviously with an eye toward the votes to be had on Staten Island. The residents there would do well if they were to recognize the hopelessness of traffic relief through this tunnel and ask the city authorities to let it stand on its merits as a freight tunnel to develop the industrial potentialities of the Island.

The Narrows tunnel issue is one which the port authority must meet no matter what the city may do, for if the Narrows tunnel is built by the city with freight connections to the Baltimore & Ohio on Staten Island a large part of the freight which would otherwise have gone through the port authority's proposed tunnel will be diverted to the Narrows tunnel and the port authority will hardly be able to demonstrate the economic necessity for its tunnel under the bay, a demonstration it is required by law to make before it can issue bonds to finance the tunnel. Just how it meets this issue will be a fair indication of whether it intends to carry out the spirit or the letter of the treaty which created it. Some years ago we pointed out that the Narrows tunnel controversy between city and the interstate body afforded a fine opportunity for the art of compromise. Now that the authority has won its first skirmish it is in an exceptionally strong position to initiate a move toward an adjustment which will work to the benefit of both sides.

Solve Complicated River Crossing with Double-Deck Bridge

New Reinforced-Concrete Bridge Across Black River at Watertown, N. Y., Has Upper and Lower Decks
—Concrete Arch Design and Construction Complicated by This Arrangement

BY E. H. HARDER

Concrete-Steel Engineering Co., New York City

A DOUBLE-DECK reinforced-concrete arch is one of the outstanding features of a grade-crossing elimination project recently completed in the city of Watertown, N. Y. This bridge, known as the Court Street Bridge, eliminates a dangerous crossing of one of Watertown's crowded thoroughfares over an important branch line of the New York Central & Hudson River R.R.

An 86-ft. flat barrel arch span of reinforced concrete now carries Court St. over the same tracks at a location a little to the east of the former grade crossing. From a point over this arch, the new grade of Court St. is

stream. With the abandonment of the old steel truss across the river, a detour would be necessary which would have greatly reduced the value for business purposes of the above-mentioned property. A lower deck carried by this 195-ft. span readily solved this problem since this deck virtually replaced the above-mentioned truss.

The double-deck arch has four ribs, each 6 ft. wide, except for a slight increase of width at the ends. The clear distances between these ribs are 13 ft., 3 ft. and 13 ft. The spread of 3 ft. between the inner pair of

BRIDGE ACROSS BLACK RIVER, WATERTOWN, N. Y., WITH TWO DECKS

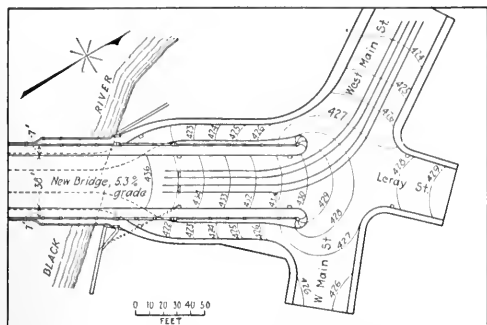

4.5 per cent to the south, toward the center of the city, and 5.3 per cent toward the north and over the Black River. From the north end of the north abutment of the arch over the railroad tracks to the south bank of the Black River, a distance of 150 ft., the structure consists of three continuous girder spans. Each span measures 48 ft. 8 in. center to center of supports.

North of these girders and spanning the river is the double-deck reinforced-concrete arch of 195-ft. span length between abutment faces. The grade of the upper deck is 5.3 per cent, and carries the new realignment of Court St. over the Black River. As so far described, this elimination project would have deprived property owners between the railroad tracks and the south bank of the river of easy access to the north bank of the

ribs provides ample room for a 10-in. gas main, a 12-in. water main and several 3-in. conduits. The city has erected a wooden enclosure to protect these mains against the extreme cold of winter.

The roadway over the upper deck is 38 ft. wide from curb to curb flanked by a 7-ft. sidewalk along each side of the bridge. Straight slab work was used throughout the upper deck because of the simplicity of construction. These slabs are supported on the four arch ribs by thin transverse walls. Reinforced-concrete girders, built into these walls, bridge the 3-ft. and 13-ft. gaps between arch ribs and carry the upper deck slabs above the lower roadways. Expansion joints were provided in these slabs at the points shown in the drawings.

Like the upper deck, the lower one also consists of

METHODS OF LAYING OUT GRADES ON APPROACH

contour lines for solving such problems have been shown in *Engineering News-Record* in the past few years.

Vehicles on the approach grades to the lower deck at the north end pass under a 39-ft. overhead girder which supports the upper deck sidewalk and part of the roadway. The minimum vertical clearance under this girder is 13 ft., while the horizontal clearance was carefully designed for the largest vans now in common use with ample margin for future increase of size.

LOOKING THROUGH THE SOUTH DECK

Each roadway of the lower deck as well as the north approaches to the lower deck is 12 ft. wide between curves except at the above-mentioned underpass where the roadway width increases from 12 ft. to 14 ft., and then decreases to 12 ft. again.

The entire structure, together with the approaches at the north and south ends, was designed by the Concrete-Steel Engineering Co. of New York City, of which William Mueser is sole owner. Mark D. Ewell was resident engineer for the designers. The work was let on a unit price basis to the Peckham Construction Co., Inc., of Buffalo, N. Y., for whom E. C. Boehm was in charge of the work. The city engineer of Watertown is Paul B. Sutton.

The final construction cost of the bridge was \$362,000, which was paid by the City of Watertown, the State of New York, and the New York Central & Hudson River R.R., according to schedules agreed upon previous to the letting of the work.

Power Progress on the Saguenay

SAGUENAY RIVER in northeastern Quebec has unusual power possibilities because the total fall from Lake St. John to tidewater, about 320 ft., is concentrated in a distance of 28 miles, and the flow which now ranges from 12,000 to 220,000 sec.-ft. is susceptible of considerable regulation on account of the fact that Lake St. John has an area of over 300 sq.mi., and a drainage area of 30,000 sq.mi. Other power sites in the Saguenay valley are located on the Au Sable and Chicoutimi Rivers, the two outlets of Lake Kenogami. The flow of these two rivers can also be regulated by increasing the storage capacity of Lake Kenogami.

Isle Maligne Power Station—The present development includes the concentration of the power of the Saguenay River in two plants, one located at Isle Maligne, a point on one of the outlets of Lake St. John, called the Grand Discharge, and the other down near tidewater, a few miles above the mouth of the Shipshaw River. Work on the Isle Maligne station, which is to have a capacity of 480,000 hp., was started in January last. Access to this plant required the building of 15 miles of railway including a bridge over both the Little Discharge and one channel of the Grand Discharge.

This development consists of a power house, four spillways, a dam to control the right channel of Grand Discharge at Isle Maligne, one earth dam, and three spillways at the head of the Little Discharge. The power house, which itself is the largest of the dams, will contain twelve 40,000-hp. units.

This work is being carried on by the Quebec Development Co., of which J. B. Duke is president, W. S. Lee and F. A. Cochran, vice-presidents. W. S. Lee is acting as chief engineer and F. A. Cochran as resident manager of the Isle Maligne work.

Chicoutimi Development—Lake Kenogami, at the headwaters of the Chicoutimi River, has a drainage area of 1,450 sq.mi. and a water surface of 12 sq.mi. The present development scheme calls for increasing this storage area to 21 sq.mi. by increasing the level of the lake 32 ft. The lake has two outlets discharging into the Saguenay, one the Chicoutimi River, 15 miles long, with a total fall of 467 ft., and the Au Sable River, 6 miles long, with a drop of 440 ft. Under the proposed storage scheme the minimum dependable flow of 1,800 sec.-ft. will be distributed on the basis of $\frac{2}{3}$ to the Chicoutimi and $\frac{1}{3}$ to the Au Sable. There are already two developments on the Chicoutimi River, one at the town of Chicoutimi, utilizing a head of 56 ft., and another of a head of 190 ft. at the plant of La Cie de Pulpe de Chicoutimi. A further head of 60 ft. is now being developed by Price Bros. On the Au Sable River, Price Bros. have already developed a total head of 380 ft.

The storage work on Lake Kenogami will necessitate the construction of two concrete dams, one at each outlet, and four earth dikes to keep water from the raised lake from overflowing into other watersheds. The construction of these dams and dikes is to be carried by the Quebec Stream Commission, which has been guaranteed a sum sufficient to cover the yearly interest, operating and sinking fund charges by the companies deriving benefit from the additional storage. O. O. Lefebvre is chief engineer of the Quebec Stream Commission.

Indebtedness to the *Journal of the Engineering Institute of Canada* and to H. G. Cochran, A. F. Dyer and C. N. Shanly for this information is acknowledged.

Highway Traffic Surveys in Nine Tennessee Counties

Determine Kind, Volume and Distribution of Traffic and Gross Load and Unit Wheel Loads on Freight Carrying Vehicles

By N. W. DOUGHERTY

Professor of Civil Engineering, University of Tennessee, Knoxville, Tenn.

DURING the summers of 1921 and 1922 co-operative traffic surveys were conducted in nine Tennessee counties by the Bureau of Public Roads, the Tennessee Highway Department, the University of Tennessee and the several counties. The surveys were planned, first, to determine kind, volume and distribution of travel, and second, to determine capacity and weights of freight vehicles by measuring gross load and unit wheel loads.

Counting stations were established on all the main highways of the several counties. The stations were established at intersections where separate counts could be made on the primary roads and also on the secondary, or feeder roads. Fig. 1 for Knox County illustrates the choice of stations. In this county 64 separate counts were made by placing the counters at 31 counting stations. To obtain weights of vehicles, weighing stations were established on selected roads of each county. Both loaded and empty trucks were weighed in sufficient numbers to give a fair estimate of freight haulage, average load and prevalence of overloading. Two loadometers were used in determining weights.

The traffic counts in the several counties were scheduled over four-day periods, beginning on Thursday and ending on Sunday. On one day of each count automobile and truck license numbers were listed. At many stations the number of vehicles passing was so large that license numbers could not be accurately listed; at such stations the counter recorded the type and direction of vehicles. During the two summers' work

FIG. 2—TRUCK HAULAGE OF LIVE-STOCK IS COMMON

number of vehicles passing, of more than 99,000, gives percentages as follows: Automobiles, 69.1, and trucks, 14.0, making a total of 83.1 per cent for motor-driven travel leaving 16.9 per cent for horse-drawn travel comprising 7.8 per cent buggy and 9.1 per cent wagon.

It will be noted, Table I, that in Hamilton County only 5.5 per cent of the total number of vehicles listed were horse-drawn vehicles. In Madison County the percentage reaches 37.1 for horse-drawn vehicles against

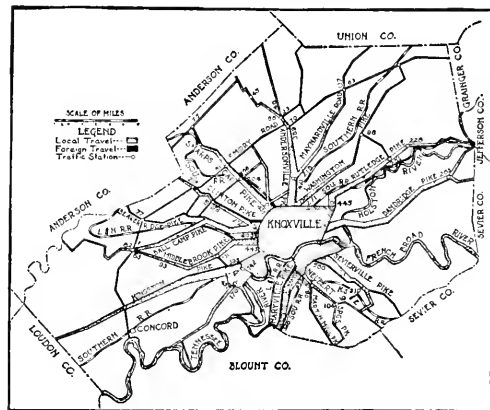

FIG. 1—TRAFFIC MAP OF KNOX COUNTY

more than 28,000 auto-license numbers and 6,900 truck numbers were listed and tabulated. The license numbers were used to determine local and foreign travel.

Kind and Volume of Travel—Traffic information was so listed that analysis could be made of the number of automobiles, trucks, buggies and wagons. A summary for the nine counties, which includes an average daily

62.9 for motor-driven vehicles. In the four larger counties, Davidson, Hamilton, Knox, and Shelby, the percentages are, autos 71.0, trucks 15.5, buggies 5.9 and wagons 7.6 making 86.5 per cent motor-driven vehicles against 13.5 per cent horse-drawn vehicles. In the five smaller counties the average is, autos, 60.4, trucks 7.1, buggies 16.4 and wagons 16.1 making 67.5 per cent motor-driven vehicles against 32.5 per cent horse-drawn vehicles.

Local and Foreign Travel—In the nine counties over 28,000 automobile license numbers were listed and classified. Table II shows this classification for the county, adjacent counties, other counties of the state and other states. The total for the nine counties gives 78.1 per cent of the automobiles on the road from the county in which the roads were located; an additional 6.8 per cent were from adjacent counties, making the total local travel practically 85 per cent. The number of cars from other states reached only 2.3 per cent of the total.

Table III shows the sources of truck traffic. Here the tabulation is for seven counties with nearly 7,000 trucks. Of all the trucks listed 75 per cent were from the county in which the roads were located. An additional 7.4 per cent were from adjacent counties, making 82.4 per cent of the truck travel purely local. Only 0.5

* Through roads.

per cent of the trucks listed were from other states. It will be noted that these trucks were listed in Shelby and Hamilton Counties whose county lines were also state lines. The truck data for Shelby County is not complete or it would show more trucks from Arkansas and Mississippi. In this county the traffic was so heavy that traffic counters could not make accurate lists of the license numbers of all automobiles and trucks passing the roads. Had such a count been made on many of the roads the percentages would run as high as that for adjacent counties.

Weighing Stations—From two to six weighing stations were established in each county. Three stations were chosen on roads where beam scales had been installed and the vehicles to be weighed were passed over the scales. Weights were determined much more quickly by scales than they could be determined by the loadometers. Stations were so selected that typical information could be obtained for each county. The information taken was very complete, giving make and capacity of vehicle, kind and value of commodity, length and direction of haul, frequency and amount of overload, kind and width of tires, and origin and destination of travel. The scope of this paper will only permit a short discussion of two of these items, namely, kinds of commodities and frequency and amount of overloads.

Commodities—Trucks are used to haul a great variety of commodities, varying from such bulk material as logs, sand and gravel to building materials as lathes, lumber and shingles, to household goods, textiles, food-stuffs, soft drinks and finally passengers. The number of separate commodities listed in each county ranges

FIG. 3—EXAMPLE OF OVERLOADED TRUCK

from thirty to fifty, depending upon the location of the county, the location of the weighing stations and the number of vehicles weighed. Fig. 2 shows a small truck in Davidson County with sheep. Many trucks in this county and adjacent counties are used to haul live-stock to market at Nashville.

Fig. 1 is plotted to show the average daily twelve-hour travel passing the several traffic stations. The width of line is proportional to the total number of vehicles passing; the dotted width is proportional to the percentage of local automobile travel and the shaded area is proportional to the foreign automobile travel. This diagram and Tables II and III show that the great preponderance of travel is local travel. Simultaneous counts taken over as much as 200 miles of roads show similar information. The road problem, therefore, in Tennessee is essentially a local problem. When the 97.7 per cent of State travel is served the 2.3 per cent of travel from other states will be able to get along.

Overloading—Approximately 55 per cent of the loaded vehicles weighed were carrying loads above their rated capacity. Trucks of all capacities from one-half ton up were overloaded. In some of the counties the overload-

ing for capacities of two tons and over amounted to 68 per cent of the vehicles weighed. Seventy per cent of the vehicles weighed were under two tons capacity while thirty per cent were two tons and over. Of the 30 per cent 19 per cent were of two-ton capacity leaving only 11 per cent for trucks above two tons. The small percentage of vehicles of two tons capacity and above accounts, in part, for the prevalence of overloading for these capacities. Fig. 3 shows a typical heavy load in Knox County. Here a four-ton truck is loaded with logs carrying a gross load of 20,000 lb. and having a concentration of 770 lb. per inch width of tread.

Regulations—The 1921 legislature gave the state highway department authority to regulate traffic on state aid roads and with county co-operation to regulate traffic on the county roads. The regulations issued by the department limit the gross load to 20,000 lb. and the wheel loads to 650 lb. per inch width of tire channel. About 25 per cent of the loaded trucks weighed were violating one or both of these regulations, 23.5 per cent had excessive concentrations on the rear axle and 2.6 per cent had excessive concentrations on the front axle as well. In Shelby County are two pieces of road maintained by the state highway department and in this county the percentage of overloading was considerably lower than in the other counties. On the two roads maintained by the department overloaded vehicles are stopped and required to unload until the regulations are not violated. Enforcement of proper regulations is badly needed in the other counties to protect the roads from the overloading evil.

Canada Spends Ten Million on Roads

Up to Aug. 31, this year, Canada had eighty highway projects totaling 785 mi., costing \$9,336,373. Of these, Ontario had fourteen projects totaling 100 mi., and Quebec six projects, totaling 110 mi.

The Economical Use of Irrigation Water Based on Tests

Solution of the Problem Considered When Water Is Available at a Given Price, Land Plentiful, Water Limited and Land Semi-Irrigated

BY HARRY S. CLYDE, WILLARD GARDNER AND ORSON W. ISRAELSEN

Assistant in Physics Laboratory, Associate Physicist, and
Irrigation Engineer, respectively, Utah Agricultural
Experimental Station

ONE of the biggest single problems confronting the western public is to determine what amount of irrigation water under different conditions constitutes economical use. During the early settlement of the West there was enough water for all and each irrigator could use the amount he wanted. With the growth of these communities more land has been brought under irrigation and nearly all the late-season water has been appropriated, resulting in a need for limiting the amount of water that each farmer may use to the most economical quantity, in order that the greatest possible irrigation development may be made.

To ascertain what constitutes economical use of water numerous irrigation experiments have been conducted in recent years. Competent engineers, agronomists and others directly interested in irrigation differ widely in their interpretation of these experiments and in the application of them to a determination of what constitutes economical use of water. This paper presents a method of interpreting irrigation experiments under

which 3 in. fell during the growing season. The experiment farm soil is a medium clay loam, rather impervious, and from 6 to 8 ft. deep. Ninety-six plots were planted with spring wheat of the staple varieties during the five years. The $y-w$ curve given for this experiment in Fig. 1B shows the average results. The yield of grain increased as the water applied increased until a depth of from 16 to 22 in. had been applied, after which more water decreased the yield.

In Figure 1B the $y-w$ curve is given also for potatoes at the Gooding Station. Results are available for applications of water ranging up to 36 in. only. Up to this point the curve shows the yields still increasing with increase in water supplied, but the rate of increase was very small.

Experiments in Utah—The Utah Experiment Station has done much work on duty-of-water investigations the results of which have been summarized in *Bulletin 173*. The experiments were conducted on a typical, deep, uniform loam having excellent underdrainage. The annual rainfall at the Utah Station varies from 15 to 18 in., of which only about 2 in. comes during the growing season (June, July, and August). The $y-w$ curves for sugar-beets, potatoes, alfalfa and wheat given in Figs. 2 and 3 are the average results of many trials in the Utah experiments.

The tests with sugar-beets, which extended from 1902 to 1919, show that the yield increases with applications up to about 30 in. and then starts to decline. There is quite a range where the yield is not greatly affected by smaller or greater amounts of water. The curve for potatoes shows the results of twenty-six trials covering fourteen years. The most favorable amount for potatoes seems to be between 30 and 40 in. Applications above 60 in. make the yield drop fast. The curve for alfalfa shows that it needs more water than other crops, the highest yield being secured with an application of 50 in. The decline in yields from larger applications was very slow. The experiments with wheat show that it is not nearly so much affected by irrigation as are alfalfa, sugar-beets and potatoes. As the applications were increased above 15 in. the yield increased very slowly.

The solution of the problem concerning the economical use of irrigation water rests upon the experimental determination of the $y-w$ curve, examples of which are shown above. With the exception of the various cost data, the $y-w$ curve gives in condensed form all the information necessary for a practical solution of the problem, which has in reality three possible solutions, one for each of three different cases.

Case 1. Water Available at a Given Price—First, let us consider the case in which there is a limited area of land and a sufficient supply of water to be had at a specified price per acre-inch. The question is to determine how much water should be used to secure the maximum profit per acre of land.

Let c = cost of the water per acre-inch, which cost includes the annual interest on money invested in water rights or shares of water stock, the maintenance of the irrigation system and the application of water. It is realized that c , as here defined, is not rigorously constant. A more accurate analysis, considering c as a variable, is presented later in the paper.

FIGS. 1A AND 1B—YIELDS AT DIFFERENT WATER APPLICATIONS IN IDAHO AND CALIFORNIA

various conditions of water supply, irrigable land, cost of crop production and value of crops produced. Before the analysis of the problem, some typical experiments in California, Idaho and Utah are briefly reviewed.

Experiments in California—Adams et al. have conducted extensive investigations with alfalfa on the University Farm at Davis, Calif. During 1910 and 1911 a tract of 8.19 acres was divided into checks averaging 0.28 acre each. From 1912 to 1915, inclusive, 3.48 acres were used for this work. The soil was classified by the U. S. Bureau of Soils as a Yolo loam. The annual rainfall during the six years varied from 12 to 24 in. During the first two years the following total amounts of water were given to different plots: none, 12 in., 24 in., 36 in. and 48 in. In 1912 two additional plots were provided which were given depths of 18 and 60 in. A stream of 0.9 sec.-ft. was used to irrigate the plots, and in most cases it was distributed through a slip-joint pipe to insure even distribution. The yield ($y-w$) curve for this experiment is given above in Fig. 1A. It shows that the maximum yield was obtained with an application of 36 in. of water, although the increase in yield due to increase in depth of water from 30 to 36 in. is almost negligible.

Experiments in Idaho—Bark² made investigations to ascertain the water requirements of various crops and soils in southern Idaho. His studies were continued five years over comparatively large areas. At the Gooding Station the average rainfall for the five years was about 11 in., of

FIGS. 2 AND 3—YIELD-WATER CURVES FROM UTAH EXPERIMENTS

w = number of acre-inches applied per acre.

b = cost per acre for plowing, seeding, fertilizing, tilling, taxes, rental value and such other costs as are proportional to the acreage.

a = price per ton of the crop on the farm, which is the market price minus the cost per ton for hauling. The cost of hauling varies with the yield and therefore could not be counted in b .

i = net income per ton.

y = yield in tons per acre.

Then cyw = the total cost of the water per acre.

$$\text{And } i = a - \frac{cyw + b}{y} \quad \text{or } iy = ay - cyw - b \quad (1)$$

Stated in words, this equation means that the net profit per acre equals the total return per acre for the crop at the farm minus the acre cost of the water and the costs per acre for plowing, seeding, fertilizing, tilling, taxes, rental value, etc.

The first derivative of iy with respect to w gives

$$\frac{d(iy)}{dw} = \frac{ady}{dw} = c$$

which is the slope of the curve representing the profit per acre, iy , as a function of w . At the peak of the profit curve, the slope is 0, and if we equate the right-hand member to 0, the derivative of y with respect to w may be obtained.

$$\frac{ady}{dw} = c = 0 \quad (2)$$

This derivative gives the slope of the $y-w$ curve at the value of w corresponding to the peak of the profit curve.

If we follow the $y-w$ curve out until we find a point where the slope of the tangent is equal to c/a , that point gives the w for a maximum profit per acre. To determine the economic w it is only necessary to obtain the $y-w$ curve and determine the ratio c/a . As stated above c is considered fixed. The price per ton or bushel is determined by market prices. Whether a is the price per ton or bushel will depend upon whether the y on the curve is in tons or bushels.

Equation (2) shows that the economical w is independent of the cost of plowing, seeding, fertilizing, etc., because the term b is not contained in the ratio

c/a , and it is this ratio which determines the economic w . It therefore makes no difference what the price of the land is or how much it costs for plowing, seeding, tilling, taxes, etc., the economic amount of water will be the same. From this solution it may readily be seen that if c is greater than 0, then the peak of the profit curve ($iy-w$) or the point on the $y-w$ curve where the tangent is equal to c/a will be to the left of the point of maximum yield. This means that where a price is charged for the water the maximum profit per acre will be obtained with some quantity of water less than the amount necessary to obtain the maximum yield.

To illustrate this case, let us consider a sugar-beet farm in Cache Valley. The $y-w$ curve for sugar-beets in this district is given in Fig. 2. The average value of the water right per share in Cache Valley is about \$30, which at 7 per cent interest would amount to \$5.60 per year. The annual assessments for upkeep of the canals amount to about \$1.25 per share. According to Connor, it takes nine hours of man-labor per acre to apply the water and keep the ditches clean. At \$0.25 an hour this would amount to \$2.25 per acre. Each acre receives approximately 36 in. Using these values the cost per acre-inch would be \$0.25 (approximately), which is the value of c for this region. An average price received for the beets is about \$5.00 per ton. The value of a is therefore about \$5.00 and the ratio of c/a is 25/500, or 0.05, which is the slope of the $y-w$ curve at the economic w . This approaches very closely the w giving the maximum yield.

If the cost of the water were \$1 an acre-inch, as it is in some parts of Utah, then the value of c/a would be 100/500, or 0.2. The point where the tangent to the curve has a slope of 0.2 corresponds to 26 acre-inches for w . Clearly the price of the water has a marked influence upon the economical w .

Case 2. Large Area and Limited Water Supply—In many arid region valleys there is insufficient water for the land available and yet irrigation is essential to crop production. Let us consider in Case 2 such arid valleys where land is abundant at a given price but where the water supply is limited. Consider further that it is desirable so to use the limited water supply as to obtain the maximum profit for the entire area. It is clear that in this case a different value of w will be obtained than that under Case 1.

Let w = amount of water per acre in acre-inches.

A = area to be irrigated in acres, which may or may not be the entire area of available land.

Q = total quantity of water available in acre-inches.

P = total profits for the entire area in dollars.

iy = profit per acre in dollars.

Then

$$A = Q/w \quad \text{and} \quad P = Aiy$$

From which we may write

$$P = \frac{Qiy}{w} \quad (3)$$

By differentiating P with respect to w in equation (3), namely, $P = \frac{Qiy}{w}$, we obtain as the first derivative:

$$\frac{dP}{dw} = -\frac{Q}{w^2} \times \left[\frac{d(iy)}{dw} \cdot w + iy \right] \quad (3a)$$

At the peak of the total-profits curve ($P-w$), the slope is 0. Then, equating the derivative to 0 and dividing out the factor Q/w , we obtain

$$\frac{d(iy)}{dw} = \frac{Piy}{w} \quad (4)$$

This gives the slope of the profits-per-acre curve ($iy-w$) at the w giving the greatest profits for the total

FIG. 4—Y-W CURVE FOR MUCH LAND AND LITTLE WATER

area, but we want the slope of the $y-w$ curve at this economic w .

Expanding equation (4) we obtain

$$\frac{d(iy)}{dw} = \frac{id y}{dw} + \frac{y di}{dw} = \frac{iy}{w} \quad (4a)$$

The derivative of i with respect to w is

$$\frac{dy}{dw} = - \left[\frac{yc - (cw + b) dy/dw}{y^2} \right]$$

Substituting for i and $\frac{di}{dw}$ in equation (4a), cancelling, adding and dividing by a , we obtain

$$\frac{dy}{dw} = - \frac{y - b/a}{w} \quad \text{for maximum } P. \quad (5)$$

Equation (5) gives the slope of the $y-w$ curve at the value of w which gives the maximum profits for the total area. That the term c does not appear in equation (5) shows that the price of the water does not influence the amount of water for each acre that will bring the maximum profit for the entire area. However, if the most economical amount of water is used on each acre, then, as the cost of water increases the total profits decrease, and as the water-cost decreases the total profits increase.

Now suppose we have the $y-w$ curve for a given crop in a given locality as indicated in Fig. 4, and we measure off on the y axis a distance equal to b/a . It is obvious that a point on the $y-w$ curve having a slope of $\frac{y - b/a}{w}$ must have a tangent at that point extending through the point P_1 on the y axis marked by the distance b/a . The point P_1 marks this distance for any case where b/a is greater than y when w equals zero. A tangent to the $y-w$ curve through P_1 would then have the required slope, $\frac{y - b/a}{w}$, and the point of tangency would correspond to the economical w . Clearly therefore when b/a marked by any point P_1 is larger than y at the point where w equals zero a line may be drawn through the point P_1 tangent to the $y-w$ curve.

If, however, P_2 is any point in the y axis less than y_0 representing the value of b/a , it can be seen at once that unless there be a point of inflection, as shown in the $y'-w$ curve, a line cannot be drawn through the point tangent to the curve. However, when this condition does arise, as represented by P_2 , it means that a profit may be obtained from dry-farming which is contrary to the conditions considered in this case. Such a condition involves other factors which are treated under Case 3.

Should there be a point of inflection on the curve, which is very improbable, a tangent may be drawn through P_2 to the curve as shown on the $y'-w$ curve in

Fig. 4, thus showing that a solution would then be possible.

Up to this point the values a , b , and c have been considered as constants, whereas in many cases they are variable and dependent on w . If by chance there should be a scarcity of water over a large area the yield might be decreased to such an extent as to increase the price of the crop. It must be borne in mind, however, that a decrease or increase in yield in one district will not have much effect upon the market price of the crop. The value of b may to some extent be influenced by w , in that w affects the amount of cultivation. Some crops require a cultivation after every irrigation to stir up the soil and prevent excessive evaporation. As more water is applied per acre it may be applied oftener and therefore increase the cost per acre for cultivation.

We may think of the cost of the water, c , as composed of two parts: C_w , the annual charge for construction and maintenance, and C_a , the cost of ditching and application on the farm. The first is known to be a constant as the charge is made equal for every acre-

FIG. 5—Y-W CURVE FOR WHEAT IN THE SNAKE RIVER VALLEY

inch. The second depends upon the area irrigated and thus indirectly upon w . The area irrigated depends upon the amount of water used per acre. As the water is spread over more land it requires more ditches and also more attention to spread it evenly. It would require more labor to spread 24 acre-inches over three acres than it would to put it all on the same acre. The value of c is represented approximately by the following equation:

$$c = \frac{C_0 + C_1 A}{Q} \quad (6)$$

Where

C_0 = total annual interest and depreciation on the construction cost and the annual maintenance and operation.

C_1 = cost of ditching and application per acre.

A = area irrigated.

Q = total quantity of water in acre-inches.

If these factors a , b and c vary with w , and we substitute in equation (4a) for i its value obtained from equation (1) and for $\frac{di}{dw}$ its value obtained from differentiating i in equation (1) with

FIG. 6—Y-W CURVE FOR SUGAR BEETS IN CACHE VALLEY

respect to w and simplifying these results, then

$$\frac{dy}{dw} = \frac{y}{w} \frac{b + \frac{wyda}{dw} + \frac{w^2dc}{dw} + \frac{wdb}{dw}}{a} \quad (7)$$

The value of wdb/dw in equation (7) will always be positive because, as stated above, b gets greater as more water is used per acre which makes the slope of the $b-w$ curve always positive. Also the influence of w upon a is very small and therefore may be disregarded. Under that assumption the term $wyda/dw$ in equation (7) becomes zero. Formula (7) then becomes

$$\frac{dy}{dw} = \frac{y}{w} \frac{b + C_1 - \frac{wdb}{dw}}{a} \quad (7_1)$$

From equation (7₁) it can be seen that increasing C_1 is equivalent to increasing b and thus the economical w is increased. This means that it will pay better to use more water per acre than to spread it over a larger area, which would require more ditches to be built and more labor to apply it.

The Snake River Valley in Idaho presents an interesting example of Case 2. Here there is an abundance of land with a limited supply of water. A large portion of these lands cannot be dry-farmed successfully. The irrigators, irrigation engineers, the water commissioners and the courts are therefore confronted with the typical duty-of-water question, namely, how much land shall the available water be made to irrigate and how much water shall be allowed per acre?

It is recognized that in many parts of the Snake River Valley, and in other similar valleys, water rights have been decreed according to the priority-of-rights doctrine in which economical use as defined under Case 2 is not rigorously required. Nevertheless the analysis is directly applicable in those localities where water-rights are not yet determined and also to readjudications of rights as occasion requires. Moreover it may be applied toward more economical use as between holders of rights to waters recently adjudicated, particularly where the water right is made appurtenant to the land.

In Fig. 5 is given the $y-w$ curve for wheat in this region. To answer the above question for wheat it is only necessary to obtain the values of b and a corresponding to this region, provided of course the $y-w$ curve were fully established.

An approximate average value of the land in the Snake River Valley is \$100 an acre. Assuming an interest charge of 7 per cent, this would give a rental cost of \$7 an acre. The labor cost of producing an acre of wheat in Cache Valley, Utah, is given by Connor⁴ as 29 hours of man labor and 30 hours of horse labor, including the labor used for irrigating. In this paper the labor used in the application of the water has been considered as part of c . Since the yield in the Snake River Valley averages from 20 to 25 bu. an acre and as farming is there conducted on a larger scale than in Cache Valley, thus reducing labor costs, the approximate labor cost for Snake River Valley is assumed to be 20 hours of man labor and 25 hours of horse labor for each acre. An approximate normal value for this labor would be 25c. an hour for man labor and 10c. an hour for horse labor. *Bulletin 943*, published by the U. S. Department of Agriculture (Cooper and Washburn⁵), gives the cost of producing spring wheat for the year 1919. These costs are probably about 50 per cent higher than normal, and this fact has been considered in selecting the values of the various items brought together under the factor b and summarized below:

ESTIMATED COSTS OF PRODUCING ONE ACRE OF WHEAT IN SNAKE RIVER VALLEY, IDAHO, CLASSIFIED AS b COSTS

Use of land or rental value	\$7.00
Taxes and insurance50
Man labor	5.00
Horse labor	2.50
Seed and seed treatment	2.07
Binder twine30
Interest and depreciation on machinery	1.20
Cost of threshing	1.25
Overhead, including minor items	1.30
Total (b costs)	\$21.12

A normal price for wheat corresponding to 25c. an hour for man labor is \$1 a bushel. This gives the ratio of b/a as 2112/100, or 21.12, which is indicated near the y axis in Fig. 5. A tangent to the curve in Fig. 5 may then be drawn, and the w corresponding to the point of tangency gives the economic w as 14.4 acre-inches for this region. This clearly is only an approximate solution as accurate cost factors for b are not available. However, this illustration serves to show that very accurate solutions may be obtained when the cost factors for b are known and when the $y-w$ curve is fully established.

Case 3. Area Partly Dry-farmed and Partly Irrigated—In many cases the entire acreage in a district is under cultivation, some of it being developed by irrigation and the remainder by dry-farming. Here again the problem arises as to how much water shall be applied per acre on the irrigated part to give the maximum profits for the total area. This case differs from Case 2 in that the land not irrigated may be dry-farmed with profit. In this case $P = P_i + P_o$, where P_i equals the profit from the irrigated section and P_o the profit from the dry-farm area.

For the solution of this case we may take the equation $P = P_i + P_o$ from formulas (3) and (4). Then using the following notation:

- i_0 = profit per ton of crop produced without irrigation.
- y_0 = yield per acre in tons without irrigation.
- $i_0 y_0$ = profit per acre for the dry-farmed area.
- t = total area of land in acres.
- Q = total quantity of water in acre-inches.

$$P = \frac{Q i_0 y_0}{w} + i_0 y_0 (t - Q/w) \quad \dots (8)$$

Taking the derivative of P with respect to w , equating to zero

and dividing out the factor Q w and solving for $\frac{d(iy)}{dw}$ gives

$$\frac{d(iy)}{dw} = \frac{iy}{w} - \frac{i_0 y_0}{w} \tag{9}$$

which is the slope of the profits-per-acre curve from which

$$\frac{d(iy)}{dw} + \frac{y d i}{dw} = \frac{y}{w} - \frac{i_0 y_0}{w} \tag{10}$$

As in case 2, substituting the values of i from equation (1) and $d i$ dw in equation (9), cancelling, adding and dividing by a , we obtain

$$\frac{d(iy)}{dw} = \frac{b + i_0 y_0}{a} \tag{10}$$

which is the slope of the y - w curve at the economical w and which differs from equation (5) only by an effective increase in the factor b .

The west part of Cache Valley, Utah, presents an interesting example of Case 3. This land may be dry-farmed at a profit. Recently an irrigation project has been formed to irrigate part of the land and the question arises as to how much land shall be irrigated or how much water shall be applied per acre. To answer this question we must know the profit per acre obtained by dry-farming and we must have the y - w curve for the crop grown on the irrigated land; we must also know the various cost factors outlined under b .

Consider for example that wheat is grown on the dry-farmed part and sugar-beets on the irrigated part. The average yield of wheat on the dry-farm in this district is approximately 26 bu. an acre. The land is worth approximately \$65 an acre. One-half of it is summer-fallowed each year. Thus, rent for two years must be charged against each crop. At 7 per cent this amounts to \$9.10 per acre. The labor cost includes that on the summer-fallowed part. The costs of producing winter wheat are given in *Bulletin* 943, published by the U. S. Department of Agriculture¹. These costs were taken for 1919 and are about 50 per cent above the average. This fact has been taken into consideration in selecting the items given below which make up the cost factor classed as b .

ESTIMATED COSTS OF PRODUCING ONE ACRE OF WHEAT IN CACHE VALLEY, UTAH, CLASSIFIED AS b COSTS	
Use of land	\$9.10
Man labor	4.25
Horse labor	3.35
Cost of seeding and seed	1.45
Binder twine20
Threshing	1.50
Use of machinery	1.90
Overhead	1.50
Total (b costs)	\$23.35

Considering the average price for wheat corresponding to these costs as \$1 a bushel and assuming an average yield of 26 bu. an acre, there would result an average profit of \$2.65 an acre, which is the value of $i_0 y_0$.

The cost of producing sugar-beets in this district is given by Moorhouse and Nuckols in *Bulletin* 963, published by the U. S. Department of Agriculture². The following values are selected:

ESTIMATED COSTS OF PRODUCING ONE ACRE OF SUGAR-BEETS IN IDAHO AND UTAH, CLASSIFIED AS b COSTS	
Use of land	\$11.70
Taxes and insurance95
Cost of machinery	5.80
Overhead and miscellaneous	5.80
Man labor	27.88
Horse labor	12.00
Contract labor	16.40
Seed	1.35
Manure	3.40
Total (b costs)	\$83.28

This gives the value of b as \$83.28. An average price for sugar-beets corresponding to these figures is \$5

per ton. The ratio $\frac{b + i_0 y_0}{a}$ is then $\frac{83.28 + 2.65}{5}$, which equals 17.2. This value of $\frac{b + i_0 y_0}{a}$ is indicated near the y axis in Fig. 6. Drawing a line through this point, i.e., 17.2 units above the origin, tangent to the y - w curve, shows the point of tangency as corresponding to a w of 21.5 acre-inches per acre, which is the economical w for this example.

Lessons from a Theater Fire

Stage Portion of Theater Destroyed, but Auditorium Not Damaged—Efficiency of Steel Curtains and Stage Vents

BY DR. E. G. FRIEDRICH
Berlin, Germany

VALUABLE indications of some essential points in theater fire protection were given by a serious fire that destroyed the stage portion of the Wiesbaden Theater last spring. The fire broke out just after the close of a performance of the opera "Rienzi" and destroyed the interior of the stage portion completely, without, however, breaking through into the auditorium.

Very rapid spread of the flames and the development of intense heat characterized the fire. The stage roof, consisting of a zinc covering on wood sheathing on

FIG. 1—BULGING OF LIGHT STEEL CURTAIN
Front and Rear Views

unprotected steel trusses, fell a few minutes after the fire department reached the scene. The smoke vents in the roof opened early, under the action of the internal pressure, and gave the fire free vent. Shortly after the fire started, the steel curtain between stage and auditorium, built of corrugated steel with angle-iron stiffening, became incandescent in its middle portion and began to bulge out toward the auditorium. It would have been unable to resist very long but for the relief of the pressure.

FIG. 2—PLAN OF STAGE SPACE

The roof vents in the stage were formed by swinging sections in the sides of a roof monitor, each swinging section being about 24 in. wide, pivoted on its horizontal center line, and weighted so as to open when the closing rope was released or burned through.

Because of the rapid destruction of the stage portion and the narrow margin by which the auditorium was saved (in view of the incipient failure of the curtain), two points have been under discussion since the fire: How the separation of stage and auditorium is to be made effective under all conditions, and how the stage space itself is to be protected.

Separation of Auditorium from Stage—It is a first principle of theater protection that a fire on the stage must be limited to the stage. This can be accomplished only by a really effective steel curtain provided with substantial stiffening and capable of resisting both intense heat and a certain amount of pressure. The Wiesbaden fire demonstrated that a curtain of corrugated steel with a few angles to stiffen it is wholly inadequate. Stronger construction is necessary. Rapid heating of the curtain should be prevented, so far as possible, and for this purpose it might be advisable to line it on the stage side with oak lagging, which would retard the transmission of the heat from the fire to the steel and serve effectively as a short-time fireproofing of the curtain.

Automatic-sprinkler protection of the curtain is also necessary, but it must be so arranged as to be itself not exposed to derangement by a fire on the stage or by mechanical actions. The Wiesbaden Theater had such a water curtain, but it was of a primitive kind, consisting of a perforated trough above the curtain on the stage side, supplied by pipes running along the stage wall and thus exposed to rapid destruction. The sprinkler piping should unquestionably be embedded in the wall or else placed on the auditorium side; both automatic and manual operation of the sprinkler system should be provided for.

Careful attention should be given also to the construction of the curtain guides. The guides must be of fireproof construction, preferably of concrete, and must be so detailed that there is no chance of the curtain canting or jamming while it is being lowered.

No openings between stage and auditorium other than the opening protected by the curtain should be per-

mitted. Even small openings for ventilation pipes or the like may prove dangerous. All existing doors and openings in present theaters should be closed or equipped with fireproof vestibule construction.

Operation of the curtain should automatically light up the auditorium. Emergency lighting is not likely to prove sufficient in case of outbreak of fire during a performance.

Stage Protection—Provision of sprinkler protection for the stage space itself (apart from the curtain water spray) is eminently desirable. The Wiesbaden Theater had no such sprinkler protection, but its merits were excellently proved in a theater fire in Hamburg years ago.

Divergent views have been expressed since the fire concerning the roof construction and venting of the stage. On the one hand it is claimed that the roof construction should be as light and combustible as possible, and that the roof vents should be greatly increased in area over present practice and should be actuated automatically by a moderate rise in temperature, so that venting of any fire will occur at the earliest possible period and the protection of the auditorium will thereby be rendered more certain. Others hold that the roof should be of completely fireproof construction, that thermostatic smoke vents are unnecessary and objectionable; and that pressure-relief openings, in conjunction with a curtain of adequate strength, are sufficient and would enable the fire to be held in check so that the stage could be saved except in extreme cases.

Doubtless the true solution lies between these two extremes. That smoke vents are necessary can hardly be questioned. Present requirements of building ordinances, which demand a vent area of 12 per cent of the ground plan of the stage, are believed to assure a sufficient vent capacity, but it is questionable whether they should be operated automatically by temperature rise. The initial spread of a fire on a stage, because of the large amount of combustible material and of dust, is exceedingly rapid, and if at a very early stage the draft were increased by automatic opening of roof vents the fire would at once become uncontrollable and it would be doubtful whether actors and the stage force could save themselves. Manual operation should therefore be provided, as well as operation by internal pressure.

Fireproof roof construction is believed to be essential, for proper safety of the occupants of the stage. Nothing will be gained for the safety of the auditorium by facilitating the collapse of the stage roof in a fire.

Operation and Maintenance—Several auxiliary points of caution are brought out by the Wiesbaden fire. The origin of the fire is believed to have been due to alcohol torches which the action of the opera required to be thrown down from a tower on the stage. Through carelessness, presumably, one of these torches was not entirely extinguished. With present-day electrical facilities there should no longer be need for open fire in any stage effect. Combustible or explosive liquids, open fires, and smoking should be banned entirely from the modern stage.

Stage floor spaces must be kept open. Scenery and properties should not be allowed to encumber the stage.

Fire department supervision should not end with the close of a performance but should continue until all spectators have left the theater and a complete inspection of the premises has been carried through.

Los Angeles—The Wonder City of America

By T. A. RICKARD

Contributing Editor, *Engineering and Mining Journal-Press*,
San Francisco

LOS ANGELES is the wonder city of the country. Its growth has been phenomenal. Its building activity has never known a drop since the war and is increasing remarkably.

To those who have not been there, the tales from Los Angeles seem to be nothing but promoters' talk. But this is not so. Los Angeles, even five years ago, had the earmarks of a boom town, but it has matured at an astonishing rate. Today it is a great industrial city. Around it and in it are three important industries, agriculture, oil and the movies. With these as a basis, Los Angeles has been building

AIRPLANE VIEW OF LOS ANGELES HARBOR

industries for supplying food, clothing and housing for its citizens, so that more and more it is becoming self contained. It grows on its own needs.

It was because of the unusual record of Los Angeles and because the work of the civil engineer and contractor follows upon such broad developments as are in progress there that *Engineering News-Record* asked T. A. Rickard, formerly editor and publisher of *Mining and Scientific Press*, and now contributing editor of *Engineering and Mining Journal-Press*, to tell the economic story of Los Angeles.—Editor.

LOS ANGELES was founded on September 4, 1781. Under the romantic name of *Nuestra Señora Reina de Los Angeles*, Our Lady the Queen of the Angels—but that was long before Hollywood! The first settlement was based upon a grant of land given by the King of Spain to twelve soldiers, all veterans of European wars. The founding of the pueblo was honored by the presence of the military governor, Don Felipe de Neve, and a group of padres from the neighboring mission of San Gabriel. That mission, started ten years earlier by the famous Franciscan friar, Junipero Serra, was the priestly sponsor of Los Angeles, which thereby is linked with the very beginning of Spanish settlement in Alta California. The spot where the Spanish flag was hoisted and the pueblo established 142 years ago is on the northern edge of the old plaza, recently selected as the station for a new union railroad terminal. At that time the site of the present city was on the bank of a small stream, whose fringe of verdure threaded a sunburnt valley. It was an arid land, save in the short rainy season, when for a few weeks it rejoiced in habiliments of tender green and short-lived flowers; during the rest of the year the dust-clouds of the desert danced unhindered over the coastal plain.

The Spanish pioneers were picturesque but idle; the pueblo was of no consequence; it languished, it stagnated, until the early part of the 19th century, when the Mexican revolution provoked a series of internal wars among the Spanish Californians, who resented dictation from Mexico and fought among themselves for control. When Juan Alvarado became governor in 1837 only 150 foreigners were resident in California. The influx of immigrants began soon afterward, and grew to a mighty flood when the cry of "gold" in 1848 lured the adventurous in every land to the hills of California. That immigration synchronized with the finish of the Mexican war and the cession of California to the United States by the treaty of Guadalupe Hidalgo, which was signed on Feb. 2, 1848, nine days after Marshall had found the nuggets at Coloma. This discovery of gold made San Francisco the metropolis of California. Seven years earlier the precious metal

had been mined in the San Fernando hills behind Los Angeles and profitable operations had attracted prospectors thither from Mexico. Even earlier finds are known to have been made in southern California during the Mexican régime, but they attracted little notice because the *haciendados* deprecated anything that might take the laborer from their fields and gardens. But although Los Angeles failed to become a gold-mining center, she takes tribute today from a mineral industry—oil—vastly more profitable than the placer diggings that drew the world's wondering eyes upon California.

While the people of northern California were rejoicing in their golden dreams, those in the south turned their attention to the humdrum business of raising cattle. For a decade Los Angeles took rank as the "Queen of the Cow Counties". That may sound unromantic as compared with *Nuestra Señora Reina de Los Angeles*, but it denotes the making of money. The large land-holdings that had survived from the Spanish dominion favored this industry; but, in the transition from Mexican to American control the titles to the old ranches were thrown into confusion by squatters; and on top of these misfortunes came a series of droughts culminating in that of 1864, which ruined the *rancheros*. The result was to change the economic life of Los Angeles, by introducing a diversified agriculture upon the small holdings into which the old estates were cut. At first grapes and wheat were the chief products. The citrus industry began in 1873; the oil industry in 1892; the moving-picture industry in 1908. In all of these Los Angeles today ranks supreme. Astonishing as has been the growth of this community during the life of our generation, its statistical record for the first four months of the current year has been even more remarkable.

The Harbor—The port of Los Angeles was known as San Pedro until 1909, when it was embraced by the city limits. There are some who have laughed at the pride of Los Angeles in her maritime approach, but he laughs best who laughs last, and in this case it is Señor Angeleno. The wharves are 20 miles from the center of the city, but the time is not far distant when the entire inter-

mediate space will be covered with homes and gardens, factories and warehouses. The harbor itself consists of an estuary protected by a breakwater. In 1922 Los Angeles imported more lumber than any other seaport in the world, namely, 1,440,000,000 board feet. This indicates an enormous activity in building operations; in which respect for three years Los Angeles has been exceeded only by New York and Chicago. It is expected that the building permits in Los Angeles for 1923 will be \$200,000,000. In March, 1921, the building permits totaled \$6,915,216; in March, 1922, \$10,964,829; in March, 1923, \$21,196,087.

The incoming traveler is given another hint of big business by noting a steamer, or tanker, that is being loaded with oil at a neighboring wharf. Los Angeles is today the biggest oil-producing center in the world, and much of her oil is being exported through the Panama Canal to the Atlantic and Gulf ports: during the first quarter of 1923 such shipment was no less than 1,143,000 tons. In April a single tanker carried 4,200,000 gal. of gasoline in bulk from Los Angeles to London.

In intercoastal trade the port of Los Angeles ranks second in the United States. During the last three months of 1922, according to the Shipping Board, the coastwise trade of Los Angeles was 2,401,464 tons, and the foreign shipping 251,963, a total of 3,171,629 tons in those three months. During the first quarter of 1923 Los Angeles did a business greater than all the other Pacific Coast ports and more than half all the intercoastal business of the United States; its "in" and "out" tonnage was 1,410,533, which included an incoming tonnage of 300,000. Foreign shipments have increased from $10\frac{1}{2}$ to $23\frac{1}{2}$ per cent during the past year. In 1921 the commerce through the port was 4,850,000 tons; in 1922 it was 10,800,000 tons. Evidently the arid eloquence of statistics is on the side of the Angeleno when anybody sneers at his claim to having a great seaport.

The Inhabitants—The streets are congested with motor traffic, the sidewalks are crowded with people, the benches in the parks are occupied all day, and the hotels are overflowing. This suggests a large and growing population. Statistics tell the story:

Year	Population	Year	Population
1781	44	1890	50,395
1800	315	1900	102,479
1850	1,610	1910	319,198
1870	5,614	1920	576,673
1880	11,183		

Evidently such a growth is too fast for accurate enumeration; any census is soon out of date. In May the population of Los Angeles was 800,000. I noticed a poster "Los Angeles—A Million—1925", and when I spoke of it to the statistician of the Chamber of Commerce, he exclaimed: "Oh, we'll be a million long before 1925". I asked: "How long?" "In 1924", he replied. Evidently they measure time not by the swing of the pendulum but by heart beats.

It is the boast of Los Angeles that it is 70 per cent Anglo-Saxon; it is peopled by men and women of the old stock, by the descendants of those who left the New England and Southern States to open up what was then the West and is now the Middle West. The census of 1920 gave Los Angeles a population of 576,673, of whom 454,542 were native-born. Of these 116,116 were born in California; the Middle West (12 States) con-

tributed 181,835; the South contributed 52,329; New York gave 50,548, and Pennsylvania 19,457. Of the Mountain States the largest complement, 8,979, came from Colorado. Los Angeles has 50,000 Mexicans, who do most of the common labor. No other large city in the United States has so small a proportion of aliens.

The growth of Los Angeles is the romance of the Middle West; it represents the migration of home-seekers from the prairies and mountains to the orange groves and rose gardens. Again let statistics tell the tale. New settlers are arriving at the rate of over 10,000 per month, say 130,000 per annum. These bring an average bank account of \$700, making \$91,000,000 in a year. To these deposits are added further sums as the new residents transfer investments from their former habitats to Los Angeles. It is estimated that 250,000 new settlers have come to the County of Los Angeles in the last 2½ years. Next is the tourist traffic. Fully 400,000 tourists reach Los Angeles by train annually, at least 50,000 by steamer, and 75,000 by automobile. Of the summer arrivals fully 20 per cent become residents.

Agricultural Development—Los Angeles, however, is not a community of tourists, valetudinarians, and idlers; it is a city of many industrial activities. Of these the oldest is the agricultural. On the surrounding plains where fifty years ago gaunt herds of cattle scraped a bare existence from the hard soil, where starving sheep wandered disconsolate amid clouds of dust, today is one of the pleasure gardens of the world. This arid land has been touched by the fairy wand of irrigation, which has first made use of the subterranean supply of water, tapped by wells and distributed by ditches, and later of the water brought on a large scale from distant fountains. The city covers an area of 370 square miles; the county, 4,076 square miles, of which not quite half is on the seaward side of the coast range, the country north of the mountains being of desert character. The county of Los Angeles is the most productive county in the United States, and it has enjoyed that distinction for more than a decade. In 1919 the total value of its agricultural output was \$61,864,479. The second county in productivity was Fresno, in California, with \$52,541,205, and the third, Aroostook, in Maine, with \$51,861,252. In 1920 the orange crop was worth \$18,965,800, which may be compared with the gold production of the State of California in that year, namely \$17,398,200. The golden fruit of Los Angeles was worth more than all the golden ore of the leading gold-producing state. In 1922 the orange crop suffered from an unusual frost, but a high price mitigated the disaster, so that the total production of crops was worth \$59,680,183 the principal items being:

Oranges	\$17,811,542	Lettuce	\$2,500,000
Lemons	3,748,000	Beans	2,284,800
Walnuts	3,412,800	Sugar beets	1,932,984
Alfalfa	3,388,000	Grapes	1,735,500
Strawberries ...	3,310,790	Potatoes	1,663,500

Oil Resources—Within four blocks of the center of the city oil is still being pumped from a number of old wells. This is the Salt Lake oil field, discovered by miners from Salt Lake City in 1892. Here Edward L. Doheny made his start as an oil-operator. In 1894 these wells produced 196,094 bbl. of oil; but that was a mere bagatelle. The industry has grown enormously during the last three years. In 1920 the oil fields of the Los

Angeles area, including the counties of Los Angeles and Orange, yielded 30,005,427 bbl.; in 1921, 35,587,492 bbl.; in 1922, 68,344,308 bbl., or just one-half of the total production of California, which was 138,236,490 bbl. The oil produced in the Los Angeles area during 1922 was worth \$96,000,000. The three principal oil fields tributary to Los Angeles (Santa Fe Springs, Long Beach (Signal Hill), and Huntington Beach) have developed greatly. Between Jan. 1, 1922, and 1923, the number of wells at Santa Fe Springs increased from 3 to 145 and their yield from 3,000 to 203,000 bbl. per day. The increase at Long Beach was from 5 to 237 wells, production from 1,100 to 144,000 bbl. At Huntington Beach there were 71 wells at the beginning of 1922 producing 13,800 bbl. per day; sixteen months later this oil field

THE OIL FIELDS OF SANTA FE SPRINGS

had 248 wells yielding 113,915 bbl. per diem. On May 1, 1923, these three oil fields were producing 460,915 bbl. daily, or more than two-thirds of the output of the whole of California. In 1921 the average daily production of the entire State was only 314,657 bbl.

The activities of the oil promoter sometimes conflict with those of the dealer in real-estate, but usually they supplement one another amicably. A realtor's sign says: "Mining rights included". That means that a man can buy a tract of land on which crops are growing and retain the ownership of any oil that may be stored in the sand several thousand feet underground; he can speculate both on the surficial agricultural products and on the subterranean mineral deposit.

Industrial Development—A community that is growing fast creates the need for new industries; it also becomes rich enough to start industries that will serve the surrounding region. The bank deposits of Los Angeles were \$284,940,000 on June 30, 1917; they were \$620,095,000 on June 30, 1922. In 1900 the products manufactured in Los Angeles were valued at \$15,134,000; in 1922 their value was \$900,000,000. Conditions are highly favorable to manufacturing on a big scale. The costs of power and water are low.

The climate permits outdoor work the year round. Conditions are such as to attract the best type of workman. Labor troubles are infrequent. Strikes are non-existent, because Los Angeles is an open-shop center. The labor-unions have nicknamed it the "scab" city, and its citizens accept that opprobrious epithet as

a compliment. It means liberty under the law. The last eruption of anarchy was in 1909, when the office of the *Los Angeles Times* was wrecked by bombs; the perpetrators of the crime are in prison. That affair outraged public opinion so thoroughly that the truce of the unions was checked effectively.

In 1910 Los Angeles was the 37th industrial city in the United States; today it is seventh. It employs 130,000 artisans. The leadership of the community is in the hands of a group of men with the ability to take advantage of the remarkable natural resources of Los Angeles, and sufficiently big-minded to work together harmoniously for what they deem to be the common interest. For example, in 1920 the market for cotton collapsed just when the crops of the Imperial valley (in California and Mexico) and the Salt River valley (in Arizona) were ready for sale. The producers faced the loss of a market for a crop that had been grown during a period of high cost, involving most of their capital, which was the working capital of a territory new economically. If they did not receive financial aid at this critical juncture, at the end of 1920, the people in these two great valleys would become bankrupt, and with their bankruptcy would go the capital accumulated in twenty years. Thereupon the Los Angeles bankers joined in extending a loan of \$5,000,000 to the banks in the two cotton-growing districts, this loan being secured by the cotton, which could not then be liquidated. Instead the Los Angeles bankers imported experienced men from other cotton regions (in Texas and the South) and developed contacts with cotton buyers; they opened a market for the cotton, and eventually moved the entire crop at a price that sufficed to repay the loan and yet leave something for the producers, who are now in process of recovering their prosperity. The result is that the people of the two cotton districts are bound by ties of friendship to Los Angeles, which is accepted as their metropolis.

Los Angeles is establishing good relations with the mining districts of the Southwest. The people of western Arizona, southern Nevada, southwestern Utah, and northwestern Mexico are being taught to look upon Los Angeles as their metropolis, as the source of capital, as the market for supplies, as the resort for a holiday. For those living in the Pacific Southwest, the harbor of Los Angeles is becoming recognized as the "front door", through which their products can be moved to market most economically. Los Angeles money is going forth into the central valleys of California and is helping to finance projects much farther afield, in Utah, Nevada, Arizona, New Mexico, and northern Mexico. Communication with the southern counties of California is facilitated by a fine system of paved roads, of which these 14 counties have 3,105 miles, besides 30,924 miles of secondary roads.

Climate—The climate of Los Angeles is one of its attractions. Meteorological records for 47 years show that Los Angeles has an annual average of only 11 days without sun, and only 15 days with as much as a quarter of an inch of rain; it can claim 273 days when the temperature is neither above 80 deg. F. nor below 40 deg. The rainfall averages only 15 inches per annum and is concentrated into a period of 40 days. The result of these favorable conditions is that Los Angeles enjoys a vigorous semi-tropical climate with all varieties of healthful weather.

The Movies—Hollywood is not a suburb of Los An-

geles; it is an integral part of the city, although its outer edge spreads among the hills, where the more notorious cinema actors have built their villas. Disreputable or not as some of them may be, they contribute to the wealth of Los Angeles. The weekly payroll of the local cinema industry is \$500,000 and the capital invested in the business is said to exceed \$20,000,000. Los Angeles produces 85 per cent of the motion pictures made in the United States. Fifty-three studios, employing 200 companies, with 15,000 regular employees and 20,000 extra helpers are producing films valued at \$170,000,000 per annum. The actors represent only 10 per cent of those employed in this business. The cost of a seven-reel picture ranges from \$100,000 to \$250,000. Most of this output is financed in Los Angeles.

Public Utilities—Such a community—growing by leaps and bounds—calls for the rapid development of public utilities on a large scale. Los Angeles suffers from growing pains: the sewers periodically prove inadequate, it is impracticable to install telephones as fast as they are wanted, the extension of the street-car system lags far behind the requirements, the schools are overcrowded, but in one respect the city has made ample provision; it has a superb supply of good water.

First, let us look at the telephone system. Los Angeles has 22.7 telephones per 100 of population, as against 4.7 per 100 in London, and an average of 12.5 telephones per 100 in the whole United States.

Second, an abundant supply of good water is essential to a large community; in this respect the men of Los Angeles showed keen foresight. They have water enough to supply a city of 2½ million people. The building of the water conduit from the Owens river across 250 miles of rugged desolate country to Los Angeles is one of the romances of public utility. The engineer who designed it—William Mulholland—fulfilled his promise to do the work in five years at a cost of \$23,000,000. In 1905 a report made for the Water Commissioners showed that nowhere in the basin south of the Tehachapi range and west of San Bernardino could an adequate supply of water be obtained for the city without interfering with the welfare of the adjacent agricultural territory. The former source of supply, the Los Angeles river, would have restricted the population to 300,000. Fred Eaton, formerly city engineer and mayor, was familiar with Inyo county and had seen the splendid stream of water that the Owens river carried from the watershed of the Sierra Nevada into the desert, where it was lost in a dead sea of saturated salt solution. To take this water would rob nobody. He bided his time, he bought lands for the purpose, he acquired options, he was prepared for a private enterprise if the city should hesitate to tackle the project. In 1907 the people of Los Angeles voted \$23,000,000 of bonds to finance the project. The vote was in the ratio of ten to one.

Five generating plants along the aqueduct develop 110,000 hp. Another 110 hp. is generated from streams tributary to the aqueduct. The total hydro-electric power resources owned by Los Angeles in connection with its aqueduct amount to 220,000 net horsepower. The city is distributing 90,000 hp. from its aqueduct system, at a cost to itself of 0.4c. per kilowatt-hour, and 25,000 hp. more that it purchases from the California Edison Co. Domestic lighting costs 5.6c. per kilowatt-

hour for the first 100 kw.-hr., and 4.1c. for the next 500 kw.-hr. For manufacturing purposes a rate of 1.06c. per kilowatt-hour for 100,000 kw.-hr., and of 0.86c. for 1,000,000 kw.-hr. is maintained.

Here, too, it is proper to mention the enterprise of the Southern California Edison Co., which is engaged in a project to develop 1,400,000 hp. on the south fork of the San Joaquin river at an expense of \$300,000,000. This power is to be transmitted at the unprecedented pressure of 220,000 volts. In 1923 this company will expend \$26,000,000, as against a budget of \$50,000 in 1900, when its generating capacity was only 12,000 hp. as compared with 500,000 hp. today. This company has 48,108 stockholders.

Real Estate Promotion—The increase of population explains the tremendous activity in house-building and the hectic condition of the real-estate market. Los Angeles has had many such booms, all of which have run their course to an exuberance that brought its own natural corrective in a temporary collapse; nevertheless the dreams of the realtor of yesterday have become the actualities of the householder of today. At the present time the property assessment of Los Angeles county is \$1,517,000,000, which is one-third that of all California. During the year ending March 5, 1923, there were erected 102,000 new buildings in Los Angeles.

As I strolled downtown from the University Club, I was asked by a pleasant voiced young woman to join an "excursion de luxe to Verdugo Woodlands", which was described as "the California Switzerland with its memories of Spain". To help the Iberian illusion, I was informed, on a handbill, that "a dainty Spanish luncheon will be served, while the breezes, whispering through the old rose vines will tell you of the historic happenings of a bygone century". The realty agent and the oil promoter adopt similar methods for beguiling the unwary. The visitor to Los Angeles is invited to a "free ride" in a handsome motor-bus to see some lovely lots in a new subdivision or to consider the purchase of attractive stock in an oil company. He hears a lecture on oil or oranges or the climate of Los Angeles from a person of the preacher type, a spellbinder to whom the promoters pay a fabulous salary, comparable with that of a 'movie' actor. The supposition that the average man grasps at something for nothing is based on good psychology, likewise the anticipation that he will be lured by the chance of making ten dollars by risking one.

Labor Conditions—Labor is being attracted to Los Angeles by the prevailing high wages. This may explain the shortage of workers at the mines of the Southwest. As I walked along the street I heard a warning: "Look out below". A man was throwing remnants of construction over a fence. The phrase he used told me that he was a miner, so I asked him where he had been working: At Jerome, in the U.V.X., he said. Even the high wages paid by James Douglas in such a rich copper mine as the United Verde Extension did not suffice to keep him in Arizona. Can you wonder? Who would not prefer to work in the sunlight, so near the seashore and the orange groves, rather than labor in the dirt and darkness underground? They come to their work in automobiles. Almost anywhere in the outskirts of the city one can see a string of cars lined up like a funeral, the cars belonging to those at work on a nearby building. Thanks to Henry Ford, the

workman can live anywhere within 15 miles of his job; when off work he can cruise about the adjoining country, and acquire the desire for better ways of living.

Yes, there are many automobiles in Los Angeles. One of the Angelenos carries the license of No. 1,000,000. That is a gasconade; it does not mean that a million licenses have been issued by the State Motor Vehicle Department, which distributes its licenses in serial groups for local distribution; however, in 1922 Los Angeles county had 275,000 out of the 840,000 motor vehicles in California. The city itself had 200,000 automobiles, or nearly a quarter of those in the State.

Her Citizens—While Los Angeles has been exploited by advertising on an extraordinary scale, it is also the product of the co-ordinated energies of good citizens. Its Chamber of Commerce today has 9,400 members, which is more than any other Chamber of Commerce in the world. In them there is "some genius of authentic love for their neighborhood, their city". They are men of the old stock; their names are easy to pronounce; they represent the diverse activities of the community. I venture to name some of them. Among the bankers: Henry M. Robinson, Joseph F. Sartori and Henry S. McKee; among the business men: Henry E. Halderman, John B. Miller, Lee Phillips, and the late Arthur Letts; among the engineers: William Mulholland, J. B. Lippincott, and Seeley W. Mudd; among the lawyers: Marshall Stimson, George A. Farrand, and Louis Hill; a publisher, Harry Chandler; a physician, John R. Haynes; an educator, Susan Dorsey, and two benefactors of great wealth, Henry E. Huntington and Norman Bridge. The gift of the Huntington library, picture gallery, and botanical garden at San Marino is an event in the cultural life not of Los Angeles alone but of California. Similarly the endowment of the California Institute of Technology at Pasadena by Dr. Norman Bridge and Arthur H. Fleming has established a center of scientific research for all California, under the leadership of Dr. Robert A. Milliken.

Man does not live by bread alone, neither on oil, nor even on oranges; the leaders of Los Angeles are awake to the fact that if their community is to hold its proper place it must provide for more than the material needs of its people, it must not count only on its tons of oranges or its barrels of oil, but on the great imponderables that make men worthy citizens of a democratic commonwealth.

Four Years Enough to Complete Hetch Hetchy

M. M. O'Shaughnessy, city engineer of San Francisco, recently made an official statement as follows: "It will take from thirty to thirty-two million dollars to build the Hetch Hetchy aqueduct from Moccasin Creek to Irvington. There are no physical obstacles in the way. If the money is provided this work can be done inside of four years and would make Hetch Hetchy water available for use not only in San Francisco, but in other bay cities." Moccasin Creek, the location of the first Hetch Hetchy system power house, is the point to which water can be delivered through works now practically complete. Irvington is about 100 miles toward San Francisco from Moccasin Creek and it is here that the aqueduct begins which is now being built for the use of the Spring Valley system until Hetch Hetchy water is available. Reference to the construction of this aqueduct from Irvington to the city appeared in *Engineering News-Record*, May 4, 1922, p. 751.

Leveling Morro do Castello in Rio de Janeiro

Fifty-Acre Hill in Brazilian City Being Cut Down and Used to Make an Extensive Fill on the Water Front

ONE of the largest city grading operations of recent years is in progress at Rio de Janeiro. The Morro do Castello, having a volume of some 5,000,000 cu.m., is being leveled and the excavated material used to add to the waterfront building area. A portion of the excavation and fill is being done by steam shovels and trains, but a larger portion is being accomplished by sluicing, using hydraulic giants to break down the material and dredge pumps to assist the sluices as the lower levels of the excavations are reached.

Covering an area of about 50 acres the Morro do Castello is a rocky elevation rising to a maximum height of nearly 200 ft. in the midst of the business section of Rio de Janeiro. On this hill and between its foot

FIG. 1—STEAM SHOVELS HANDLED SOME HUNDREDS OF THOUSANDS OF YARDS

and the waterfront was the original settlement of the city. Before the improvement it was crowned with old forts and church edifices dating back to the sixteenth century, around which huddled the homes of a mixed Latin population. Virtually it had become the city's slums, into which business did not crowd because of inaccessibility for commercial traffic. Also this high land lying between shut off the ocean winds from a large section of the city. To improve these living conditions but more especially because leveling the hill and using the excavated material to build out the shore line would add some 200 acres to its business area, the city decided to cut down the elevation, fill in beyond the old sea wall and build a new sea wall embracing the fill. The plan of this improvement is indicated in Fig. 2.

As indicated by the contours, Fig. 2, the hill has rather abrupt sides. By its removal the area gained for building will be about 185,000 sq.m. or about 46 acres. The area formed by the fill is 612,000 sq.m. or about 151 acres. The volume of material in the hill was estimated as 3,000,000 cu.m., approximately, 25 per

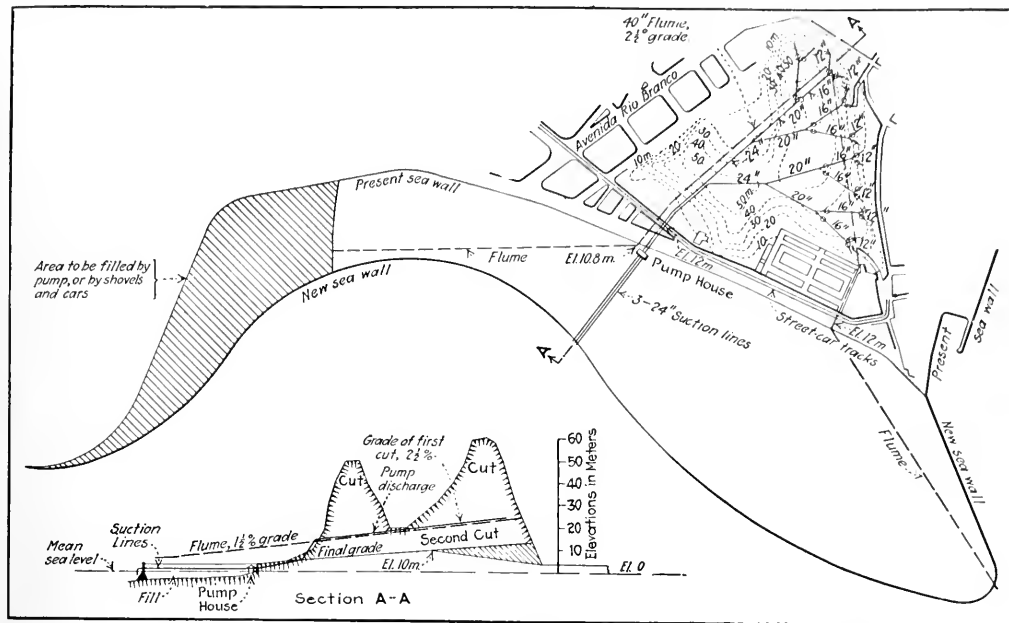

FIG. 2—PLAN OF 5,000,000-CUM. LAND RECLAMATION OPERATIONS IN RIO DE JANEIRO

cent of which is rock. About 3,500,000 cu.m. have so far been removed from the excavation into the fill. As previously stated, part of the excavation and fill was by steam shovel and trains and a larger part by hydraulicking.

Steam Shovel Work—At the outset the city began work with light German shovels using locomotives and flat cars, motor trucks and mule carts, to transport the excavated material. Later, when American bankers undertook the financing of the work and Leonard Kennedy & Co., Inc., of New York City were made administrators of the operations for the city of Rio de Janeiro, American equipment was installed throughout, except for two German light shovels retained for cleaning-up operations. The enlarged outfit comprised, then, the two German shovels, two railroad-type coal-burning, American shovels, four 30-ton locomotives, forty 12-cu.yd. automatic air-dump cars and one 15-ton locomotive crane. This outfit was put in operation in July, 1922. A view of the steam-shovel excavation is shown by Fig. 1.

Excellent service is reported of all the equipment. The large railroad shovels load from 150 to 250 cu.m. an hour, depending on the materials and the train service. The material is hauled from 1 to $1\frac{1}{2}$ km. and dumped behind a granite quay-wall, which is also a part of the project. The trains consist of eight cars each, and their operation is somewhat delayed as they cross a busy street at grade. Owing to the proximity of the work of the city, all blasting has to be done very carefully and is expensive. Besides the area marked as filled by shovels and cars, considerable other fill is being placed by them because they are available and by being kept busy are earning money. However the great bulk of the fill is being put in by hydraulic methods.

Hydraulicking Operations—As stated, about three-quarters of the hill is decomposed granite, weighing about 98 lb. a cubic foot and consisting of 62 per cent sand and rapidly settling particles and 38 per cent clay and slow settling materials. The binding material separates freely from the sand when water strikes it. A study of the situation indicated that, by gravity sluicing, about 2,250,000 cu.m. could be removed with flumes located 7 m. (23 ft.) above street-car tracks at crossings, the cut being started at El. 12 (m.) and running to El. 23 at the point of the hill farthest from the pumps. On Fig. 2 this is indicated as "first cut." Later the second cut could be removed by the same

FIG. 3—DREDGE PUMPS IN PIT BOOST MATERIAL INTO ELEVATED FLUME

flumes by hydraulicking to sumps and pumping into the flumes. Briefly this was the plan adopted, the general arrangement of pumps, pipe lines and flumes being as shown by Fig. 2. Of course there is no fixedness of location of the dredge pumps nor of flumes and pipe lines, but the drawing indicates the general plan followed.

Broadly the equipment divides into the pumping plant, the pipe lines and the monitors for breaking down the ground; the sluices and dredge discharge pipe lines; and the dredge pump units, of which two are semi-stationary and two are removable.

The pumping plant for the hydraulic giants, Fig. 2, consists of three units each with its separate suction line of 24-in. pipe. Each unit consists of three 16-in. centrifugal pumps in series, designed to deliver 7,500 gal. a minute against 475 ft. head. Each is direct-connected to a 1,200-hp. motor. The three units deliver into a cast-iron header from which the two 24-in. discharge pipes extend into the pit and divide into branches as indicated by Fig. 2. The pipe sizes decrease

direct-connected to a 500-hp. motor, with 30 per cent speed control, mounted on skis. Two of these are a semi-permanent location on the beach and two in temporary locations at the hydraulicking pit, Fig. 3. These pit outfits are moved up toward the base of the hill as the excavation progresses. All pumps are primed by means of water ejectors, there being a special dredge-type enclosed flap valve immediately connected to the pump on the discharge side. The pumps are designed for 8,000 gal. a minute against 120-ft. head. As indicating performance, at the time of writing, the beach pumps are averaging each 235 cu.m. of solids an hour. The average of the pumps in the pit is 202 cu.m. of solids per hour. One pit pump is discharging through a 212-m. line with a lift of 9 m. and the other through a 555-m. line with a lift of 11 m. The average coefficient of friction is 5.6. The percentage of solid handled ranges from 5 to 13 and averages about 10.

Between the pit and beach sumps open flume is employed. It is 40-in. semi-circular steel with about 45

FIG. 4—LARGE PORTION OF 150-ACRE FILL PLACED HYDRAULICALLY

from 24 in. to 20, 16 and 12 in. The 12-in. pipe reduces to 9 in. at the giants, which range from 150 m. to 900 m. from the pumps.

At the sea ends the suction lines have 24-in. Newmann continuous-service foot valves with galvanized steel screens. As the pumps are primed, by means of vacuum pumps the foot-valve flaps were removed and large check valves were used in the 20-in. discharge lines. Owing to the rapid tropical sea growth it is necessary once a week to raise and scrub with steel brushes the outside screens and once in two or three months to remove the entire foot valve and clean the inside screens. Rising-stem gate valves are used for controlling the discharge. In the hydraulicking pit it has been found a time saver to substitute a lever for the valve stem handwheel, it will close the valve against pressure much faster than will the wheel. The giants have 4-in. tips. Fig. 3 shows the pit with giants in operation.

The first cut in the upper part of the hill above El. 15 was gravity sluiced directly to the fill. Below this level dredge pumps in the pit lift the material into the sluices which deliver to a sump on the beach whence other dredge pumps force it through pipe lines to the fill. One of the pit sumps and pumping plants is shown by Fig. 3, and Fig. 4 shows the discharge pipe lines on the fill.

There are four dredge pumps, each 16 in., semi-steel

per cent of the section lined with cast-iron plates. The most efficient grade has been found to be $3\frac{1}{2}$ per cent. The pipe lines from the beach pumps to the fill are 16 in. in outside diameter, with sleeve couplings. Two kinds of pipe have been installed, one a $\frac{3}{4}$ -in. lap-welded steel and one a special-analysis hard steel. No comparison of wear is yet possible.

As previously stated Leonard Kennedy & Co., Inc., of 67 Wall St., New York, are the administrators for the City of Rio de Janeiro. The work was organized by A. D. Chisholm, with J. W. Armstrong as chief engineer, T. E. Siebenthal in charge of the steam-shovel operation and Nathan H. Jones in charge of the hydraulic work, with D. V. Nystrom as general foreman of the latter operation. The work is now in charge of Nathan H. Jones.

Disinfectant on Garbage Fills

The sanitary fills made in Portland, Ore., as a means of garbage disposal are sprayed with a deodorant consisting of 21 parts of pinoleum to 25 parts of water, which is used when the wind blows from the fills toward residential districts, and with a disinfectant made up as follows: To 1 gal. of carboic acid is added 3 oz. of caustic soda and $\frac{1}{2}$ lb. of rosin. This compound is mixed with 100 gal. of water and is then sprayed on the fill.

Development of High Efficiency in Centrifugal Pumps

A Description of a Recent Program of Experimental Design Carried Out
in the Hydraulic Laboratory of the University of Michigan

By A. F. SHERZER

Assistant Professor of Mechanical Engineering,
University of Michigan, Ann Arbor, Mich.

AMONG the various ways in which centrifugal pumps may be classified one based on their so-called specific speed appears to the writer the most rational. The term specific speed applied to the centrifugal pump has somewhat the same meaning as its perhaps better known relation to the water turbine. Mathematically it is expressed as follows:

$$N_s = \frac{RPM \sqrt{GPM}}{H^{\frac{3}{4}}}$$

The value of the specific speed thus computed establishes the performance of a pump with regard to its three most important elements, speed, capacity and head. The efficiency of a centrifugal pump is often represented as a function of its specific speed.

Another important and very useful method of classification is with reference to the capacity. This is regarded by some as of such importance that the efficiency is expressed as a function of the capacity alone. The fact of the matter is that probably neither method alone will give altogether reliable results and a method based on a combination of the two would be more useful and accurate. This was discussed, at some length, by the writer in *Engineering News-Record*, June 30, 1921, p. 1114.

From an examination of the data published in various books and technical articles one is apt to reach the conclusion that pumps of low specific speed are inherently of low efficiency. One author calls attention to this, adding the remark that for this reason no effort is made to produce such pumps. This article has been prepared for the purpose of indicating approximately to what degree such opinions are justified.

A pump of low specific speed is seen to be one which discharges a relatively small quantity of water against a relatively high head at a moderate rotative speed. Such pumps are easily recognized by the large diameter impeller of narrow width.

This leads to another means of classification of centrifugal pumps with reference to the ratio of diameter of the impeller to its width. Such a method has proved extremely helpful as applied to water turbines and no doubt can be used fairly successfully for the centrifugal pump. Various reasons are assigned for the low efficiency usually found in pumps of low specific speed. From among them two are worthy of special mention, (1) disk friction and (2) internal leakage. By disk friction is meant the power consumed by the friction of the impeller rotated in water, which varies with the diameter as the fifth power. The pressure or head developed varies only as the second power. This indicates (a) that the disk friction increases at a much greater rate than the pressure and that the efficiency is thereby reduced; (b) that it is more efficient from the point of view of disk friction to develop a given pressure with a small diameter impeller at a high rotative speed than with a larger diameter impeller at a lower rotative speed, the peripheral speed being equal in each case. (2) Internal leakage: The high-pressure water is in most pumps prevented from

leaking back into the suction of the impeller by means of a very close running fit between the impeller and the stationary walls of the casing. Some designers, in addition to a close fit, employ a so-called labyrinth packing so designed as to increase greatly the length of the path the water must take in its flow through the clearance. The amount of this internal leakage or short circuited water varies with the clearance and the pressure and while it may be but a small percentage of the total pump discharge in the case of pumps of large capacity it should be noticed that expressed in the same way it may represent a considerable part of the discharge of a small pump. This internal leakage means that the capacity of the pump will be reduced by that amount and, worse yet, that power is required to circulate this water, which further increases the power required to drive the pump.

From this it will be seen that we are, in general, limited in two ways in the design of centrifugal pumps for low specific speed.

In spite of the apparent certainty of low efficiency the writer contends: (1) That there is a real demand for pumps of this type, and (2) that if properly designed they may have very satisfactory values of efficiency.

When from the above considerations it appeared likely that the pressure would be too high and the quantity too small for good efficiency the required pressure was developed in two or more stages. This naturally results in an increase in the size and cost of the pump as now two or more runners are required. If a single-stage pump could be designed to do the work it would probably be much cheaper, lighter, occupy less space, and cost less for maintenance and repairs than would a multi-stage pump.

The usual pressure limits for small single-stage pumps (300-600 g.p.m.) seems to be about 150 ft. for best efficiency, although some higher values are found and in some cases some lower limits have been set by their designers.

During the early part of 1919 the writer was engaged in developing a new line of pumps for an eastern manufacturer. This company had formerly built very excellent pumps of European design which were not particularly well suited to American practice. The principal reason for this lay in the fact that owing to the construction of the pump the weight increased very rapidly when designed to receive the larger diameter runners required by current American practice in order to meet the available motor speeds.

The writer's past experience had led to the belief that it would be possible to build pumps for considerably higher heads per stage than were usual at that time and that if properly designed and constructed the efficiency need not be unacceptably low. In order to learn to what extent this might be true a 3-in. pump was designed for a capacity of 400-500 g.p.m. and heads around 200 ft. at a speed of 1,750 r.p.m. Nothing very definite was prescribed and the whole design was mainly

for purposes of study. There were no unusual features connected with this design except that the impeller was of greater diameter and narrower width than the writer had ever designed before. This naturally called for greater care and workmanship in the foundry and machine shop. The ratio of width of the impeller divided by its diameter was in this case about 1.76, which was very extreme indeed, a value which has not often if ever been exceeded.

This pump was built in 1919 and tested the early part of 1920. The test results for a speed of 1,730 r.p.m. are shown in Fig. 1. The actual test results were a little different from those expected but nevertheless were very satisfactory indeed. A maximum efficiency of over 60 per cent was obtained at a discharge of about 520 g.p.m. against a total head of 180 ft. A comparison of the results secured by this design with the multi-stage pumps offered for those conditions by other manufacturers indicated that its performance was fully as good as had often been obtained by the use of two or more stages. Other very desirable characteristics were obtained as well. Fig. 1 indicates that the pump was adaptable for a very wide range of operating conditions with but slight change in efficiency. A very flat power curve was also obtained. The specific speed of this pump, as computed by the formula $N_s = \frac{N\sqrt{GPM}}{H^{3/4}}$ is approximately 800.

Prof. R. L. Daugherty in his book on centrifugal pumps shows that for a volute pump having a specific speed of 800 the probable efficiency would be about 52 per cent and that for a pump having an impeller with a ratio of width to diameter of 1 to 76 the probable efficiency would be about 35 per cent.

If we recall that the pump built and tested by me developed an efficiency of over 60 per cent under the conditions named above the figures are very significant and indicate rather unusual performance.

While the writer was still engaged in study and analysis of the test data secured from this pump he was called to the University of Michigan to take over the course in Hydraulic Machinery formerly given by Prof. S. J. Zowski then on leave of absence. The final results of the study made on the performance of this pump seemed so worthwhile that the experimental development of this type of pump was begun in the hydraulic laboratory of the University of Michigan. In April, 1921, the second pump of the series was tested. The results for a speed of 1,700 r.p.m. are given in Fig. 2. The tests on the original pump had indicated more or less clearly the best lines of procedure and these were embodied as far as possible in the second design. Although considerably different in design these two gave about the same characteristics. The diameter of the runner in Pump No. 2 was greater than No. 1 and hence somewhat higher pressures are obtained even at a lower rotative speed. This increase of both capacity and pressure was obtained with no loss of efficiency or of any of the desirable characteristics of the original design. Pump No. 2 was built from an entirely new set of patterns for both the shell and impeller.

As an interesting application of the possibilities of this new development it occurred to the writer to design a pump for such conditions of capacity and pressure as were prescribed for fire service. Accordingly the designs were prepared without delay for a pump to deliver 750 g.p.m. against a total head of 231 ft.,

CHARACTERISTIC CURVES FOR 3-IN. EXPERIMENTAL PUMPS NOS. 1, 2, 3 AND 5

equivalent to a pressure of 100 lb. per square inch. To reduce the expense as much as possible, as well as to permit the use of a portion of the existing patterns,

this pump was also designed as a 3-in. pump having a 4-in. suction. Obviously better results would have been obtained had the pump been built as a 5- to 6-in. size as was subsequently shown by later tests. This pump was tested in June, 1921. Fig. 3 gives the characteristic curves of the pump when tested at 1,750 r.p.m. Fig. 4 shows the equal efficiency curves for the same pump at speeds of 1,750, 1,450 and 1,150 revolutions per minute. Attention is called to the extremely flat efficiency curve in Fig. 3 as well as to the wide range in capacity and pressure with relatively high efficiency shown in Fig. 4.

The pump developed a maximum efficiency of 64 per cent at a capacity of 750 g.p.m. against a head of 240 ft. at 1,750 r.p.m. The results of this test exceeded all expectations by a considerable margin, and it is believed that, everything considered, it established a record not yet equalled in European or American practice. The underwriters specify that a pump offered for this service shall be an 8-in. two-stage design and that the efficiency shall not be less than 55 per cent, the expectation being that it will vary between 55 and 60 per cent. Later tests indicated that several per cent could have been added to the efficiency by an increase in the size of the pump. Inasmuch as an efficiency of 64 per cent was actually obtained under the conditions named, it is probable that had this pump been designed as a 6-in. instead of a 3-in. pump the efficiency would have been not far from 68 per cent. This would be fully as good if not better than that developed by the average multi-stage pump for these conditions.

It should be pointed out that these results were obtained with a simple volute pump without the use of any guide vanes or diffusers. This still further confirms my belief that guide vanes and diffusers are entirely unnecessary in pumps of careful design and equally good results can be obtained without them. The writer is well aware that others may still prefer to use them but maintains that it is possible by proper design to secure the same results without.

In the light of this the results obtained from this 3-in. pump are surprising to say the least. The average pump offered for the same service would weigh in the neighborhood of 2,000 lb., while the total weight of the pump whose results are shown in Fig. 3 was only 412 lb. This indicates that it has been possible to reduce the weight of the pump from about 80 per cent with little or no loss of efficiency. The cost of this pump would be somewhat in the same proportion although probably not as extreme a variation. The writer believes that this design has established, by a considerable margin, a new record for large capacity and high pressure with light weight. Strength was in no way sacrificed in this design and the pump would be amply safe under much higher pressure than it was called upon to meet.

Up to this point efficiency had been considered of secondary importance and no especial attempt had been made to secure high efficiency. The previous designs were primarily for the purpose of study and it was desired to see what values of efficiency might be obtained.

Space does not permit an account of the various tests, studies, etc., which were undertaken with these designs but it will be sufficient to say that after a careful study of all the test data there were strong indications that an improvement in the efficiency was possible. With this in mind a new impeller was designed

for somewhat lower capacity and pressure in order to keep within the easy test range of the dynamometer. This design was undertaken in an effort to improve the efficiency without disturbing the other desirable characteristics previously obtained, such as the extremely flat efficiency curve. This impeller was tested the latter part of 1921. Fig. 5 shows that my prediction of increased efficiency was fully realized.

A comparison of Fig. 5 with Fig. 2 shows that an increase of about 7 per cent in efficiency was obtained by this new design. It was also considered likely that the new design would show even less variations in efficiency with varying capacity than had been obtained with the previous pumps. This too was borne out in the subsequent tests. A remarkable feature of this pump is the unusually wide range of capacity and head—more than half the total possible—for which the efficiency is 60 per cent or better. In other words this pump will develop within 35 per cent of its maximum efficiency at half its normal capacity or about 5 per cent more than is usual in such cases.

After a careful study of these tests it was thought that by proceeding in a slightly different direction it would be possible to still further increase the efficiency of this type of pump. Owing to the pressure of other matters the work on this pump was at a standstill until in August, 1922, the design of a special pump primarily for high efficiency was undertaken. This pump was designed for smaller capacity but about the same pressure as those in the past. The tests were made in November, 1922, with the results shown by Figs. 6 and 7.

The increase in efficiency hoped for was obtained together with some improvement in the operating characteristics. The maximum efficiency was increased from 67 to 68.5 per cent or $1\frac{1}{2}$ per cent in spite of the decrease in capacity from 650 to 425 g.p.m. This makes the results even more remarkable as the usual effect of a similar reduction in capacity is a decrease of 3 to 4 per cent in the efficiency.

For the same capacity and pressure the efficiency was increased from 62.5 per cent in Fig. 5 to 68.5 in Fig. 7, a total of 6 per cent. Without regard to the high efficiency developed by this single-stage pump at heads around 200 ft. the curves of Fig. 7 are interesting for their broadness. The efficiency at half load is about 86 per cent of its maximum which is higher than usual by several per cent. The effect of this is very evident in the tests at lower speeds. For instance the development of 67 per cent efficiency with a discharge of only 275 g.p.m. under 80 ft. head at 1,150 r.p.m. is not exceeded by any pump which has come to the writer's attention. In efficiency, operating characteristics, etc., it is the equal of many of the 4- and 5-in. two-stage pumps offered for such service by manufacturers today. The total weight of this pump was 380 lb., which is perhaps half or less that of a two-stage pump offered for this service with no better efficiency.

The writer hesitated to publish the results of this work until such a time as he could be sure that these pumps had been in operation a sufficient length of time to warrant the belief that their initial satisfactory performance would be maintained in the future. To date nothing has occurred to indicate that they have any difficulties inherently connected with them, and they seem perfectly normal in every respect. Fig. 8 will

give the reader an idea of the general construction of these pumps. Ball bearings of the radial-thrust type furnished by the Gurney Ball Bearing Co. were used on all the pumps. Otherwise there were no particularly novel features affecting their general appearance. The operation of the ball bearings was highly satisfactory in every case. The tests were very carefully conducted and check runs were always taken to secure accuracy.

EQUAL EFFICIENCY CURVES FOR 3-IN. EXPERIMENTAL PUMPS NOS. 3 AND 5

The power was measured by means of an electric dynamometer, the pressure by calibrated test gages and the speed with a highly accurate form of tachometer. The results may be regarded as correct within a very small margin. The pumps are entirely of commercial design and are in no way to be considered as freaks. The workmanship and materials were first class in every respect.

The writer hopes that this brief account of the development of this type of pump may prove to be the means of stimulating further work along these lines. An exceedingly bright future is predicted for this type of pump if adapted to commercial requirements, as it seems to have all the good characteristics of multi-stage design with few or none of their well known disadvantages. It should be understood that many of the refinements of design used in the production of these rather high pressure pumps are entirely applicable to those for moderate pressures. The efficiency of centrifugal pumps is known to vary with the capacity, other things being equal. This variation is rather well known and has been represented by various curves showing this relation. For volute pumps having a capacity of 275 g.p.m. the probable efficiency would be about 60 per cent in the usual case. For pumps of about 4,000 g.p.m. efficiencies as high as 85 per cent have been obtained.

The pump shown in Fig. 7 is seen to develop about 7 per cent more efficiency than the usual design. It seems not at all improbable that by the use of these same methods of design the efficiency can be raised about that amount all along the line. This should result in maximum values of efficiency in the neighborhood of 90 per cent and one long-hoped-for dream of the pump designer—that of equaling the efficiency of the water turbine—would then have been realized.

Rehabilitation of the Kansas City Southern Ry.

Study Made for Systematic Improvement—Grade and Line Revision—Track Rebuilt—Bridges Strengthened or Filled

LIGHT original construction to meet financial conditions, with subsequent extensive rehabilitation and improvement to develop operating economy and traffic capacity, has been the history of many American railways. This condition, as illustrated by the Kansas City Southern Ry., is presented in the annual report of that company in a reprint of an address by L. F. Loree, chairman of the board and an engineer of wide railway experience. Some brief extracts from this address are given below. The original line was described in *Engineering News*, Feb. 17 and March 10, 1898, pages 116 and 162.

The Kansas City Southern Ry. was a conception of Arthur Stillwell, whose purpose it was to bring Kansas City into connection with the Gulf of Mexico by the shortest practicable route. Partly by new construction and partly by the purchase of small lines, the road was completed and opened for operation in 1897. The difficulties both of location and construction had been very considerable. The traffic was thin, 887,108 tons being hauled one mile per mile of road in 1905; the bridges were light, having been built for Cooper E-31 loading; the rail was light, 60- and 56-lb. per yard, and was badly surface-bent because laid on dirt ballast. Sidings, yard and terminal facilities were inadequate. The grades on no division were less than 1 per cent and increased in the mountains to 1.8 per cent.

The new owners who took over the road in 1905 proceeded at once to deal energetically with these conditions; first in overcoming the more outstanding defects, while careful and painstaking study was made of the problems of maintenance, operation and traffic. The services of an experienced engineer, supplemented by a large field force, were secured to study the possibility and cost of grade reductions. These studies extended over 1906 and 1907,

and the conclusions reached have been closely adhered to in the subsequent development.

In the modernization of the property, the roadbed both in cuts and on fills has been widened to a standard cross-section, and much attention has been given to surface and sub-drainage, especially in the gumbo soil of Missouri. The line has been relaid throughout with 85-lb. rail and with the improvement of the condition of the main line rail has gone a corresponding improvement in that of yards and sidings. Each year a substantial percentage of the cross ties used has been subjected to preservative treatment until now 51 per cent of the ties in main track are treated. About 90 per cent of the line has been raised 6 to 12 in. on gravel or chat ballast, while some material has already been applied to the remaining 10 per cent. The line and surface, and generally the maintenance of the track, compare favorably with other lines in the South-western territory.

A carefully maintained bridge program has been followed, looking to a reduction in the number and length of

Old Cast-Iron Structures on British Railways

REPLACEMENT of a cast-iron railway bridge 88 years old and of cast-iron columns of a trainshed 69 years old, on two English railways, is reported in the *Railway Gazette* (London). The bridge, built in 1835, has a span of 50 ft. It carries four tracks across the Regent's Canal in London, near the Euston terminal station of what is now the London, Midland & Scottish Ry., so that an enormous main-line traffic has crossed it. In view of the great increase in weight of English locomotives during the past few years the removal of the bridge is not surprising, especially as it had been strengthened several years ago.

This bridge had three shallow through trusses of the bowstring type, each truss consisting of two parallel flat arched ribs of I-section with vertical spandrel members and a horizontal top chord over the full width, as shown herewith. The two sets of spandrel members were connected at intervals by cross frames. Wrought-iron hangers carried cast-iron cross-girders or floorbeams. In 1892, however, intermediate steel floorbeams were placed, suspended from the chords and ribs by steel slings or stirrups, the attachments being so adjusted that these steel members carried all the live- and dead-load. Cast-iron plates formed the floor

CAST-IRON TRUSSES OF ENGLISH FOUR-TRACK RAILWAY BRIDGE

The third truss (right-hand view) is partly concealed by a modern plate girder span carrying a fifth track at the right.

wooden trestle openings and to the strengthening of all bridges to permit heavier loading. Several trestles are now of the ballasted deck type and of creosoted timber. The new bridges have been built for the Cooper E-50 loading, and two are of large size, one over the Kaw, built in 1917, costing \$225,000 and one over the Arkansas, now under construction, estimated to cost \$270,000.

The passing sidings have been progressively extended, their total having been lengthened 34 per cent, until this work is now about two-thirds completed, and they will accommodate the longest trains moved by the heaviest power over the lowest grades. Water and coaling stations have been revised to suit the changed conditions of traffic, water treating plants have been installed where water conditions are bad, and five gravity coaling tipples have been built, as well as adequate facilities for storing and delivering oil fuel for locomotives.

The traffic offered the Kansas City Southern Ry. is low grade freight such as lumber, coal and grain, that must be moved at low rates. In order to obtain a profit from the business, a movement as nearly balanced north and south as possible is necessary. The margin of profit is sharply reduced with the traffic out of balance and might entirely disappear with a large amount of empty mileage. Further, it must be moved in heavy trainloads and with a minimum of lost motion or delay. It was with these difficulties of operation in mind that the late Horace G. Burt, in presenting his exhaustive field investigation, reported that a line might be practically realized of a maximum gradient of 0.5 per cent. More than \$5,000,000 have been spent for grade reduction, and the property is now operated as five divisions of 0.5 per cent, one division of 1 per cent and one of 1.35 per cent maximum grade. These changes in grade have yet to be pursued to a finality.

originally, but a plank deck with wood stringer for each rail was laid about twenty years ago.

The new five-track bridge will consist of six parallel plate girders with transverse floorbeams carrying brick jack-arches and a concrete waterproofed deck for ballasted tracks.

The trainshed roof of the Paddington terminal station of the Great Western Ry., at London, built in 1854, was supported by round cast-iron columns on cross-shaped bases resting on small brick pedestals of the same form. For the renewal of these columns, two steel bents were erected at each column in succession, carrying I-beams which were wedged up to carry the arch rib supported by the column. The old column was then taken down and the brick pedestal replaced by a more massive concrete pier, with anchor bolts for the steel column base, as the brick pedestals were hardly adequate for the loads. The new column was then set, a 4-in. downspout inserted, and the column adjusted to position, after which the space between downspout and column was grouted. These columns, also of cast iron, are of octagonal section 15½ in. in diameter at the head and 17½ in. at the base, with a length of 24½ ft. After final adjustment, the bents were released, to transfer the load to the column, the column bases were cased in concrete, drain connections were made and ornamental cast-iron caps and bases were placed. The columns along one platform have been renewed and the work is to be completed before winter.

Through the Reclamation Country

By F. E. Schmitt

Associate Editor, *Engineering News-Record*

A SERIES OF ARTICLES on Federal Land Reclamation is to start in *Engineering News-Record* in a few weeks. It will give a history of the twenty-one years of government irrigation, state the many problems of operation—engineering, agricultural and financial—analyze the various complaints that are being so emphasized by those who are seeking a reform of the current law and methods and seek to present some views as to a constructive policy in the future. Through it all will run the evident theme that irrigation, from planning, through construction to operation, is a continuing engineering problem.

As a part of the preparation of the series Mr. Schmitt is now traveling through the West, visiting irrigation projects, studying developments and interviewing builders, operators and settlers. He will write a series of letters of running comment on the situation as he sees it on the ground. These are not the final result of his trip but they will serve to acquaint our readers with the actualities of reclamation as revealed to an unprejudiced investigator.
—Editor.

Washington, D. C.

ON THE WAY to visit some federal reclamation projects I find that local observers of government doings believe that quite a muddled situation has developed out of the current mixture of federal reclamation and politics. Three months ago the Secretary of the Interior killed off and buried, decently or otherwise, the 21-year-old Reclamation Service, which in long and faithful performance had come to be close to the hearts of engineers and incidentally had made several million acres of desert bloom more or less like a garden. He erected a Reclamation Bureau on its grave, and converted a politician into a statesman by making him Commissioner of the Bureau. The facts, the Secretary in effect explained, condemn the engineer-controlled Reclamation Service; hence the Bureau. But now, three months later, he appoints a "fact-finding commission." So at last we are to be instructed with facts. Will they show that the Service should have been kept alive?

To my question, "What is the new commission for?" one man I met here answered, "Smoke screen!" The next man, equally shrewd though of different type, gave the same answer, "Smoke screen." The coincidence is striking. People close to the government naturally see its seamy side. But is it significant that the official action of one of the ten highest government personages should be promptly and spontaneously impugned as political subterfuge? And this action concerns a matter of outstanding national importance; not merely the welfare of a hundred thousand people on the farms, not merely the soundness of an investment of more than a hundred million dollars of the people's money, but the future development of our remaining unused land, with all that it means in production and in home-making.

They say in Washington that the Secretary has been unpleasantly surprised by the widely expressed disapproval and distrust aroused by his A. P. Davis-D. W. Davis coup d'état; that he is now trying to divert attention from it and perhaps build up a basis for new claims or policies which will lead people to forget the case of the engineers and of the late lamented Reclama-

tion Service. If this is correct, it is about the first time that the engineering profession has made its voice heard and has dented the hard shell of a government official outside its own ranks. The protests of engineers, it is true, were backed by those of many newspapers which know something about reclamation. Nevertheless, the engineering profession has cause for some slight rejoicing.

There are plenty of predictions that the new Congress will take up the reclamation subject aggressively, as of course it ought, in view of the importance and urgency of the matter. But quite apart from politics the situation is obviously a big national problem, in which the Davis-Davis incident is merely a symptom and not the trouble itself. Such local evidence as records of committee hearings of the past year or two shows that there is much complaining in the irrigated areas of the West; and the complaints seem to mean that a cost burden of \$40 to \$80 per acre for water-supply works alone, plus annual operating charges, plus cost of land leveling, is a heavy load on a farm that lies far from markets and has to compete with fertile land amply watered by nature. Some of the reclamation areas are reported to be seriously in trouble, while others, with very likely the same kind of people on them, are clear or are coming clear. There is room for a good deal of fact-finding. Besides, men informed on personalities tell me that part of the complaining has come from kickers—kickers by temperament or by profession—and does not represent the sentiment of the genuine hard-working farmers along the ditches.

There is one phase of the matter that has a family interest. Just ten years ago this journal printed a number of protests concerning the difficulties against which the reclamation farmer must labor, all of them amounting to the assertion that his first four or five years are the hardest and that he cannot begin to repay the reclamation cost so early. "Let up on him during his pioneer years" was the burden of the protests. The protestors of the past two years have said exactly the same things, although their particular projects have been producing for six to ten years now. Is the reclamation farmer still pioneering? If he is ever going to pull out of the hole why are the present protests largely duplicates of the old ones? The situation doubtless has changed; but it is easy to keep on with an old line of talk, even though new talking points have grown up. Just how the situation has changed, and what new hardships have developed to take the place of those of 1912 and 1913 also needs to be found out.

Panama Canal Tonnage Increases

The net tonnage of vessels transiting the Panama Canal during the fiscal year which ended on June 30, 1923, showed an increase of 63 per cent over the tonnage for the same period last year, this year's figures being slightly over 18,600,000 tons. Another interesting fact concerning this movement through the canal is that with very few exceptions the number of vessels each month is slightly greater than the number in the preceding month so that whereas the number for July, 1922, was 206, the number for June, 1923, was 417, which figures would indicate that the growth in canal traffic is increasing regularly. The toll collection from the 3,967 vessels which transited the canal during the past year was \$17,500,000. Net profit on Canal tolls now amounts to about \$500,000 monthly.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Dealers' Profits on Cement to Large Users

Sir—The issue of Sept. 6, 1923, is before me, and I note your editorial remarks concerning the analysis of federal income tax reports of several cement companies and the conclusion based thereon by H. Parker Wills as outlined on page 407.

As a buyer of cement, I see no just cause of complaint, either as to the price which the mills receive for their product, or the profit which their returns show they are receiving from the use of their capital. There is a somewhat uncertain and irregular business, in that it is subject not only to seasonal fluctuations but also to all the chances and changes which both local and world conditions tend to bring about.

What the state and municipal authorities are trying to do, as I understand the situation, is to bring about a change in the marketing methods of cement companies which will result in the placing of the states, counties, and municipalities on the same basis as the local dealer. We object seriously to paying a tribute of from 25 to 60c. per barrel to the local "representative" of the mills, despite the fact that his only service to us is to write an order for the quantity we may need. We are perfectly able to write these orders for ourselves, have our own storage, and in all cases take the cement from the car with our own labor and trucks.

We have the cash to pay for the goods, and yet we must pay tribute to a dealer in every case, although in many cases, the dealer does not sell in a year as great a quantity of cement as we often use in a month in the busy season.

It is this, to us, unfair attitude of the cement mills which has caused the agitation for state-owned cement mills and which will keep up this or other equally ill-advised agitation until some relief is given the user of cement in large quantities. We will not forever go on paying a tribute for which there is no justification in sense or reason. And if at some time in the near future the cement makers find themselves in the same fix with the railroads they will have only themselves to blame.

Nearly two years ago, the writer, with the board of commissioners of this county, was invited to dine with the officials of one of the great cement companies of the middle west, the object of the getting together being to try to arrange for the use of their cement on our work. During the discussion of the matter we frankly stated that so long as we had to do business with them through a local dealer, and pay an unreasonable tribute to him, we would never be found among their customers, and we further stated that at the coming session of the state legislature we were planning to have action taken which would place counties and municipalities or any one else buying their product in car lots on the same basis as their regular dealers, so far as price was concerned. Their reply to this was that so far as their particular company was concerned they were willing to make such an arrangement but owing to the "Association" rules they could not act alone; the matter was in process of being threshed out at their meetings and they had no doubt that within a year we would be able to buy their product on a dealers' basis. We have used a great many cars of cement since that time, but have not been able to buy any of it without the local dealer "getting his," nor have we bought any from that particular mill until last month when we bought two cars through their dealers at and below the price we have been paying a dealer representing another company whose ideas of "profit" were more nearly in line than theirs had been heretofore. If to regain our trade, which they had lost, they could cut their "mar-

gin" in one case 76c. per barrel and in another 87c. per barrel, it would seem that there never had been any legitimate foundation for their prices.

The cement makers are "in bad" with the public, and, the public does not always stop at reasonable concessions from those who it feels have unjustly dealt with it. It is high time the cement makers took note of the storm signals and began to throw a little oil on the waters. It will prove as effective and much cheaper than a price cut after state-owned mills are in operation. They are entitled to all the profit which their returns show they are getting from their business, and what the public is demanding and will get sooner or later is not so much a reduction in price as it is a reduction in the "spread" between the mill and the job.

While the product of the cement mills was a new and comparatively unknown quantity, there was an excuse for maintaining a dealers' organization as well as an association of manufacturers, who by their combined effort could at comparatively small expense carry out the advertising campaigns necessary for putting before the possible consumer all the facts and arguments which might induce him to try their product. But at this time with every one familiar with the use of cement it would seem that their efforts and money could be better spent perfecting their product and bettering their marketing facilities and methods, than in supporting an "association" upon which the people look with disfavor—however innocent its purpose—and which is more and more attracting the unfavorable notice of the courts.

If Mr. Wills' analysis is based on truthful and fair returns from the companies considered, their profits are certainly conservative and no one should have any quarrel with them. But when we go to their mill door with the cash in hand to pay for our cement, we do not like to be referred to some dealer to whom we must pay tribute before our wants can be supplied.

O. T. REECE,
County Engineer, Neosho County, Kansas.

Erie, Kansas,
Sept. 10, 1923.

Reproduction-Cost-New Measure of Value

Sir—Recently I had occasion to reread your editorial comment in the issue of June 7, 1923, on the decision of the Supreme Court in the Missouri telephone case, and apparently your view is that the minority opinion of the court is the more sound, namely that legitimate prudent investment should be the rate base instead of cost of reproduction at the date of inquiry.

It seems to me that your editorial as well as other advocates of the prudent investment theory neglect two factors which are of prime importance.

1. While original investment is stated in terms of dollars, the real investment was labor and materials. The total amount of these constitute the capital invested and the investment should be measured by these rather than by the fluctuating dollar. If the investment is measured in these terms, the prudent investment becomes essentially equal to the reproduction cost. The difficulty lies in considering dollars as capital instead of merely a medium of exchange of capital or elements of ultimate value. A fair return on the real investment of capital should be provided, and this return should be in terms of the medium of exchange in vogue or applicable at the time the return is being contemplated. Reproduction cost is essentially this investment quoted in terms of the currency of the time of inquiry.

2. As a practical procedure, the term "prudent investment" offers no advantage over "fair value," for "what is prudent" or "what is imprudent" is quite as vague as "what is fair," each having to be determined by evidence and judgment.

Moreover, as a practical procedure, records of additions can be as readily kept in terms of material and labor as in terms of dollars. As a matter of fact, the record is necessarily kept in both forms, although more conveniently summarized or tabulated in terms of the common medium, dollars.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

The Tehachapi Railway Co. has been organized in California with a capital stock of \$1,000,000 for the purpose of constructing 30 miles of railway in Kern County, Calif., between Ilmon and Bena.

American Bridge Co. Was the Lowest Bidder for the construction of 19 steel barges for the U. S. Government to be used in the construction of the new dams on the Ohio River. They are to be ready for use in the spring.

Reports That the Great Northern Ry. Co. plans to build 80 miles of new line from a point near Java on the southern border of Glacier National Park to Augusta, Mont., are stated to be without foundation by the chief engineer of the Great Northern Ry.

To Relieve Congestion Arising from the fact that the 4½-mile tunnel under the Severn River frequently is inadequate to carry the volume of traffic between England and South Wales, the Great Western Railway Co. has announced its intention to construct a bridge across the river at Beachley, a short distance above the tunnel.

Three of the Four Main Piers for the Bear Mountain-Hudson River bridge have been completed up to the bridge seat level and the fourth will be completed some time this month. The company will then be in a position to set the cast-steel tower bases and start the erection of the steel towers. Work on the approaches is well under way.

Bids Are Being Asked for the reconstruction of the substructure of the Georgia-Alabama bridge over the Chatahoochee River at Eufaula, Ala. The present wooden latticed-truss bridge was built about 1837 and the brick piers were built in 1855 to replace the original wooden ones. These piers are to be encased in concrete and the wooden trusses replaced by steel ones as soon as the necessary legislative enactment is obtained.

Reports from Mexico State that that country has announced plans for the creation of three free ports—one at Salina Cruz, one at Port Mexico, and one at Guaymas. A fourth will be added in the future at Rincon Antonio on the Isthmus of Tehuantepec. These free ports are based on the successful free ports of Europe and comprise areas where commercial operations not intended for consumption in the rest of the country are free from customs duties and regulations. They also provide reservoirs for storing material pending shipping orders. This announcement follows one from Belgium that 650 acres have been allocated to this purpose at Zeebrugge.

Japan's Great Earthquake Described by American Engineer Eye-Witness

John W. Doty, President of Foundation Co., New York, Viewed Destruction of Yokohama, Sept. 1, from Deck of Ship at Pier Which Collapsed During Shock

The effect of the great earthquake which devastated cities in Japan, Sept. 1, as seen through the eyes of an American engineer, is told in the following diary of John W. Doty, president, The Foundation Co., New York. At the time of the shock Mr. Doty was in Yokohama harbor as a passenger aboard the Canadian Pacific steamship "Empress of Australia," which was just on the point of casting off from her pier for her return voyage when the disaster occurred.—EDITOR.

ON SATURDAY, Sept. 1, at 11:45 a.m. all passengers were aboard the *Empress of Australia* in Yokohama harbor, the gangplank was removed, and the ship was ready to sail. The tug was alongside. Several hundred visitors were on the pier adjacent to the ship waving farewell. The ship lay with her bow toward the shore, her starboard side along the pier, about 1,200 ft. from shore. From the stern of the ship the pier projected out into the harbor another 600 to 700 ft., its total length being about 2,200 ft. Lying directly astern of us on the same side of the pier was the *Steel Navigator*, a ship of United States registry, and on the opposite side of the pier was the French liner *Andre Lebon*. Both of these ships had gangways on the pier.

At 11:57 a.m. when every one anticipated that we were leaving the pier, a tremendous vibration of the vessel was felt and it was immediately apparent

that a serious earthquake was taking place. Many people on the pier adjacent to the vessel fell to the deck of the pier and the two-story warehouse shook violently and seemed to sway laterally and vertically 12 or 14 in. throughout the first shock, which lasted from 40 to 60 sec. More than half of the pier from the bow of the ship to the shore collapsed and disappeared, leaving only the stringers on a few piers above the water level. From the stern of the ship the center of the pier for a distance of about 300 ft. collapsed and disappeared. The portion of the pier directly adjacent to the ship, on which stood the two-story Customs warehouse, remained standing. The collapse of the pier threw a great many people into the water. A portion of the breakwater encircling the harbor settled from 8 to 10 ft., some of it disappearing.

BUILDINGS COLLAPSE

Immediately our attention was called to the buildings which had collapsed along the water front. The Oriental Palace Hotel, the Grand Hotel, the Standard Oil Building, and other buildings along the Bund had fallen and it was apparent that most of the structures throughout the city had collapsed. As the buildings in the city collapsed a great cloud of dust arose from the wreckage and obscured a clear vision of the shore. The people on the portion of the pier which had not collapsed sought shelter by finding their way over the wrecked portion of the pier to the shore. Others sought shelter on the steamships *Steel Navigator* and *Andre Lebon*. As soon as our gangway openings could be unfastened ladders were sent down the side of the ship to take on board the few persons remaining on the pier. This was about 12:05 p.m. During this interval a number of other serious shocks occurred and, the dust cloud having lifted, it could be seen that the city was on fire in many localities. The tug left the side of the ship and the wind rose to a hurricane, blowing from the shore a few points off our port bow at a velocity of 60 to 70 miles an hour, making it impossible to turn the ship from the pier.

In the meantime the fires on shore united to make a complete chain of fire around the city and, fanned by the gale, swept towards the water front. At 12:30 p.m. the whole city was on fire and the heat coming over the ship was so great that the fire hose, which had been manned, were played over the decks of the ship. Two oil tanks on the ship's launch were thrown overboard. From this time the heat was intense and a large quantity of burning mate-

Automobile Association Plans to Broadcast Road Information

The national headquarters of the American Automobile Association in co-operation with the Radio Corporation of America will broadcast the latest information on road conditions every Wednesday night at 8 o'clock, Eastern Standard time, from Station WRC at Washington, D. C., which station has an effective consistent radius of 500 miles. While attention will be given to road and touring conditions based on data supplied by the National Touring Bureau, accident prevention, handling traffic, road building and maintenance will be discussed by recognized national authorities. Information of sufficient importance for use in this way may be sent to the American Automobile Association.

rial and cinders fell on the decks, and many of the small boats, lighters, junks, etc., all over the harbor, were set afire and, as their mooring lines burnt, drifted among the ships.

1 O'clock—The heat was so intense that the fire service was barely adequate to keep the exposed surface of the ship wet down. In addition to this, the force of the wind driving the heat and cinders and other debris into the faces of those operating the hose was at times blinding and it required relays of men at short intervals in order to keep the ship properly protected. Before this time it was quite evident that no one on shore could have survived the heat who had not escaped from the city prior to the joining together of the fires. Many had been forced by the heat into the water and could be seen floating around the bay in great numbers on timbers and other wreckage. The wind was so great that it was impossible to lower any life boats, and besides, every man aboard was fighting to his utmost to save the ship from fire. Those steamers which were able to get away from the piers and inner anchorages left for the outer bay. A small Japanese freighter drifted against the *Empress* but, fortunately, did no serious damage.

The *Steel Navigator*, which was lying directly astern of us and whose captain was ashore and subsequently found to have been killed, dropped one of her anchors immediately after the first shock of the earthquake and as the gale increased dropped her second anchor.

2:30 O'clock—It being apparent that, due to burning material carried by the wind and the intensity of the heat from the shore, the two-story Customs warehouse, which stood on the pier immediately adjacent to the ship, would take fire, and on account of the closeness of this warehouse, a matter of some 20 or 30 ft., the *Empress* tried to back away from this portion of the pier and in so doing the anchor chain of the *Steel Navigator* fouled her port propeller. This left the port propeller and engine useless, and in addition to this the chain was so engaged with the propeller that it acted as an anchor astern. By this time the Customs warehouse was afire and it was only the energy and courage of the officers and crew that saved our ship from taking fire until the shed had collapsed and the flames had somewhat subsided. At 4:30 o'clock the wind changed direction slightly and lessened in velocity. Innumerable burning small craft were drifting around and against the *Empress* and the danger of fire from this source continued very critical.

5 O'clock—The worst of the fire hazard was over and the wind had sufficiently subsided to permit several ship's boats to be lowered and sent to the shore for rescue work. The shore fires continued to rage all around the bay as far as one could see and many of the larger warehouses and buildings which had resisted the early ravages of the fire now burnt fiercely. The refugees commenced to arrive on the ship, many of them suffering from injuries and practically all of them from eye trouble caused by the heat and smoke. None of them had any but the clothes they stood in, and in most cases these were very few as they had used their clothes to wrap around their heads to protect them from the heat and smoke. At midnight the fires were still

raging and could be seen all over the sky-line. Barges were burning in the harbor and many of the large fuel oil storage tanks were afire and exploding.

OIL IN HARBOR BURNS

On Sunday morning most of the fires on shore were dying down but the surface of the harbor was covered with large pools of oil which had escaped from the exploding tanks. This oil was burning at various points, the largest fire, however, being directly against the shore in front of the Bund and about half a mile from the ship. This fire traveled along the shore until it reached the wrecked pier and commenced to follow the line of the pier out towards the ship. The flame of burning oil was at least 300 ft. in diameter and 150 to 200 ft. high. It became apparent, from the accumulation of oil around the ship and in many pools on the surface of the harbor, that with the approach of the fire from the shore the ship would have to move immediately. As the port propeller was out of commission and it was hazardous to try to operate the starboard engine for fear of also fouling it in the same anchor chain, the captain of the *Empress* requested the *Steel Navigator* to tow us back clear of the wharf, which was done. When we were some 200 ft. clear of the end of the pier anchor was dropped to avoid collision with nearby ships, and the engines were tested to ascertain whether or not they could be used. It was found that the port propeller could not be used but that the starboard propeller was clear.

As the ship lay in a pool of oil and the fire was still rapidly approaching along the line of the pier, and it was practically impossible to navigate through the number of ships lying at anchor in the harbor, the captain proceeded forward and by skillful maneuvering directed the ship from the danger zone through the entrance of the inner harbor, and anchored nearby. Unquestionably the anchor fastened to the anchor chain which had fouled our port propeller had broken loose or lifted clear of the harbor bottom. Otherwise, this maneuver would have been impossible. At 7 o'clock Sunday evening the oil had drifted out from the inner harbor and was again collecting around the ship. The tides and currents were in such a direction that it was dangerous for a crippled ship of the size of this one to attempt to move without assistance and an oil tanker in the harbor aided the *Empress* to turn about and reach water considerably beyond the oil pools. From that time the *Empress of Australia* was not in serious danger.

During all of Sunday the refugees continued to arrive on the *Empress* and to be received irrespective of condition, class, or nationality. There were probably 1,500 refugees on board. Many of these were seriously injured and practically without clothing, and it was impossible to move about the ship without encountering numerous cases requiring attention. It is remarkable the efficient service which the doctor and his staff rendered, not only to those slightly injured, but to many refugees with major injuries which required his personal attention. A number of volunteers ably assisted the doctor and his staff and did very efficient first aid work. The manner in which the officers and personnel of the ship received, cared for and fed the refugees is beyond commendation.

Reclamation Commission to Meet Oct. 15

First Session of Fact Finding Body Announced—Members Tell Work of Willingness to Act

A meeting of the fact-finding commission appointed recently to investigate conditions under which work in the Reclamation Service is prosecuted has been called by Secretary Work for Oct. 15. This will be the first gathering of the commission. Though seven nationally prominent men were first invited to become members of this commission, one, Elwood Mead, of California, is out of the country, and therefore will be unable to serve. The others who last week notified Secretary Work of their acceptance of his invitation to act are Julius H. Barnes, president of the U. S. Chamber of Commerce; Oscar E. Bradfute, president of the American Farm Bureau Federation; Thomas E. Campbell, former governor of Arizona; Dr. John A. Widtsoe, former president of the state university and the state agricultural college of Utah; and David W. Davis, former governor of Idaho and present commissioner of the Reclamation Service. James R. Garfield, who has but recently returned to this country, has been notified of the meeting Oct. 15, though he has not yet formally accepted Dr. Work's invitation to serve on the commission. Another member of the commission added during the week is Clyde C. Dawson, authority on irrigation law.

Secretary Work advised the members of the new commission that every facility at the disposal of the Department of the Interior would be placed absolutely at their service; that he wished every phase of the situation gone into thoroughly, and that he would appreciate a blunt and unvarnished report of conditions precisely as they may be found to exist, whether good or bad.

PUBLIC WILL GET FACTS

The Secretary explained further that when the report of this commission is completed he shall present it in toto to the President, Congress and the public.

The commission is asked to ascertain the whole amount of money expended by the Government and returned to it; the total sum owing but not due, and the amount due but unpaid; the relation between estimates and final costs; between expenditures and returns represented by structures, and to suggest the best approved methods of accounting, if not already practiced; the construction costs and methods employed to get water to the land; the methods of application of water in agriculture; original estimated costs of projects with actual costs; estimated time necessary for completion with actual time intervening; number of acres proposed to irrigate with actual number under irrigation; estimated costs per acre to water users before the work was begun and the actual cost when completed; whether the service lent itself to promotion or sought to determine possibilities and requirements of the locality; whether the government has obligated buyers of water to a higher acre cost than first proposed; if rates charged are impossible of payment from the land; if the government service is adequate; if the government has kept faith with the settlers by fulfilling its obligations for water supply; and if delinquencies have been unavoidable.

Grant Smith Dies

Was Head of One of Country's Largest Construction Companies—Activities of Organization Nation-Wide

Grant Smith, founder of the contracting firm of Grant Smith & Co., an organization which grew from a single small St. Paul firm to a group of associated companies operating all through the United States and Canada, died in St. Paul last week suddenly of heart trouble. He had just returned from a visit to his New York office the day before he died. He was 59 years of age at the time of his death.

Mr. Smith was born in Portage, Wis., in 1864. At an early age he entered contracting work and while still in his early twenties formed an association with E. V. and W. E. Hauser, both of St. Paul, the firm name becoming and remaining Grant Smith & Co. One of the first jobs taken by the firm was a subcontract on the construction of the Chicago Drainage Canal. The firm later took on numerous larger contracts, among the projects being revision of the shore line of the Great Northern Ry. into Seattle, and considerable municipal work for Seattle and Milwaukee. Activity of the organization in the Northwest became conspicuous between 1906 and 1910 when Grant Smith & Co. had a 70-mile contract on the construction of the Spokane, Portland and Seattle Ry., a Hill enterprise, and several contracts for the Canadian Northern and the Canadian Pacific Ry's.

NEW YORK FIRM ESTABLISHED

In 1911 Grant Smith & Co. & Locher was established in New York. This firm held contracts on the construction of the Catskill Aqueduct, the New York Barge Canal and two large rock contracts for the government in the Soo and Detroit Rivers. This company built that part of the aqueduct from 14th St. to 106th St., Manhattan. The name of this branch of the firm was changed in 1914 to Smith, Hauser & MacIsaac, a firm which has been active in river and harbor work in and near New York City since its inception. Smith, Hauser & MacIsaac also built during the war Camp Meade, the Curtis Bay Ordnance Depot at Baltimore, and the Ben Franklin Signal School.

During the war Grant Smith & Co. built the first wooden ships for the government in yards on the Pacific Coast at St. Johns, Ore., and at Grays Harbor, Wash. The original contract called for the construction of 50 of these vessels, most of which were built before the armistice cancelled contracts on half a dozen or so.

About twelve years ago Mr. Smith formed a Canadian branch known as Grant Smith & Co., & McDonnell. Headquarters were in Vancouver, and the activities of the company extended all through Canada, the company at the present time having charge of the construction of the extension into James Bay of the Timiskaming & Northern Ontario Ry.

Heavy Rains Destroy Trestle, Wrecking Burlington Train

The washout of a 110-ft. timber trestle spanning Cole Creek adjacent to its confluence with the Platte River near Casper, Wyoming, was responsible for the wreck of a Burlington train Sept. 28 in which about two score lives were lost. Heavy rains falling continuously during the 24 hours prior to the wreck had swollen the creek, which usually has a dry bed, into a raging torrent. A freight train had passed over the trestle but two hours before the wreck, and the roadmaster, on the train, had reported that there was no evidence of weakness in the trestle. A trackwalker had reported the structure safe an hour after the freight passed.

The locomotive and four cars were thrown into the water and the cars were either washed downstream or buried in the debris and sand. More than a score of passengers were rescued from the roof of a partly-submerged sleeping car by means of a rope suspended in midair from the car to the shore. About 80 passengers were said to have been on the train.

Civil Engineers to Have Earthquake Committee

The president of the American Society of Civil Engineers has been authorized by the Board of Direction to appoint a committee to collect information on the effect of earthquakes on structures. This is a result of the Japanese disaster. The appointment of the committee is the result of a letter by Col. John Millis, Corps of Engineers, U. S. A., to President Lowth calling attention to the great amount of information which would doubtless result from the Japanese earthquake and the necessity for collecting and collating that information for the benefit of future designers. A meeting of several of the members of the society was called with the representatives of the other national engineering societies, as a result of which a resolution was adopted recommending that the American Society of Civil Engineers undertake this study with such co-operation of the other national societies and the national societies of other nations as could be given.

President Lowth has not yet selected the personnel of the committee for this special study.

Birdseye Party Escapes Colorado Flood

Fear for the safety of the U. S. Geological Survey party headed by Col. C. H. Birdseye now making a trip down the Colorado River was set at rest by direct news received Oct. 2, from Peach Springs, Arizona. The party emerged from the flood-swept Grand Canyon, escaping by climbing through a crevice to high ground. From a safe eminence they saw the flood wall of water sweep the canyon. Noticeable rise in the Colorado's flow warned the party of impending danger in plenty of time to escape to high ground. There are ten members in the party.

Random Lines

Rubbing It In

A week or so ago a New York contractor went all the way out to Denver to close a contract he thought he was going to get for the construction of the Moffat tunnel. They treated him pretty rough in the high country. Not only did they award the contract to another fellow nearer home but on the way to his hotel a footpad held him up and took \$200, a diamond ring and his watch away from him.

Building a La Mode

Sir—Some years ago I saw in your building a very wonderful train of automatic machinery assemble the magazine—I have occasion to use a similar train to assemble the parts of a building, and it occurs to me you might be able to put me on the right track, as to whom I should apply.

I have just been to the Aeolian Co. and they agree to make me a controller, similar to that on the player pianos. I intend to take an architect's plan, enlarge it to full size, by photostat, mark on it every pipe, heating and ventilation duct, electric conduit, etc., accurately, cut it in strips, suitable to pass through their controller, punch holes in it, similar to those now in use on the music rolls. Corresponding to these holes will be a series of pipes or rubber hose, these pipes will connect with the various machines, which do the particular thing required by the hole in the plan.

By pumping air, or by suction of vacuum, we can move or stop the rheostats, which shoot the juice, into the motors of our various machines.

What I want is to meet manufacturers of automatic machines, suitable for my purpose. I can see no reason why I cannot equip a factory, and turn out sections, which will clamp together, just as the sections of a bookcase do; except that my sections will only be of such size, as would fit in a box car, as I would have to ship them, to their destination complete.

Do you think it would be possible to arrange with your company to have an article published, describing this process? I desire to get the general opinion of the engineering profession, to pass on this, which I believe is a method whereby 75 per cent of the cost, and 90 per cent of the time, now consumed in building, can be saved. I have interviewed numberless architects, builders, and manufacturers of building material, and I have yet failed to meet a single man who did not commend my purpose: that there is disagreement as to the best method of attaining it, is of course to be expected. I would therefore like to put the problem squarely before the American public, and see whether or no they care sufficiently for their so-called liberties, to back up a 100 per cent American revolution, against the menace of oligarchy.

J. A. H.

This highly practical scheme, submitted in all seriousness, is herewith placed before the engineering profession for opinion.

Railroads to Co-operate With Port Authority

Belt Line on the New Jersey Side of
New York Harbor to Be Set Up
by Trunk Railroads

The immediate outcome of the concurrent hearings before the Port of New York Authority and the Interstate Commerce Commission held during the week of Sept. 17 is that the carriers' operating committee and the engineering staff of the Port Authority are now working together to determine what improvements in operation of the marginal railroads in New Jersey can be effected at once through physical and operating changes along the lines proposed by either or both parties. As soon as this first step in the improvement of port facilities is well under way, similar co-operative studies will be made to determine the exact location of the middle belt line west of Bergen Hills in New Jersey, which line the carriers now agree should be completed as promptly as possible.

MARGINAL RAILROAD

The marginal railroad in question, known as Belt Line No. 13 of the Port Authority's comprehensive plan, is made up of sections of track of the various railroads along the west side of the Hudson River at New York and extends from Port Lee on the north, to Constable Hook near Staten Island on the south. The sections of track which make it up are now operated by the various railroads more or less independently, but during the war they were operated as a belt line and the Port Authority, as the first step in putting its so-called Comprehensive Plan for the development of the Port of New York into effect, called upon the railroads to set up this belt line again and arrange for its unified operation. Opposition to this plan, on the part of the railroads, resulted in two hearings before the Port Authority and the Interstate Commerce Commission sitting concurrently, at which times the railroads were called upon to show cause why this belt line should not now be put into effect. The interval between the two hearings was provided in order that the railroads might have time to prepare their arguments after hearing the case as presented by the Port Authority. But instead of coming forward at the September hearing with arguments against the proposed belt line, the railroads came forward with a resolution signed by fourteen officials of the principal railways affected, in which they stated that they were of the opinion that no consolidation of existing tracks into a belt line nor their unified operation was necessary at this time, and that the existing facilities were ample to handle the current traffic and any normal increase, but that facilities at interchange points should be provided in order to insure economical and expeditious handling of traffic. These facilities included increasing the capacity of the West Shore R.R. yard at Kings Bluff, certain interchange tracks and crossovers, interlocking devices and automatic signals, an estimated cost of about \$500,000. In addition to this, the presidents of the three railroads principally affected agreed to appoint a supervisory operating agent to direct the movement to, from, and over their joint lines. The railroad companies also presented a second reso-

Greene Starts Investigation of N. Y. Barge Canal Bureau

Investigation of the New York State Department of Public Works under the superintendence of Edward S. Walsh, present commissioner of canals and waterways under the reorganized Department of Public Works, was begun Oct. 2 by Supreme Court Justice Joseph A. Kellogg acting as a special commissioner. The hearing into the administration of the canal bureau was directed by Governor Smith at the instance of Col. Frederick Stuart Greene, present superintendent of the State Department of Public Works, following charges made by Col. Greene that \$70,000 paid for supplies bought from the General Mill & Contractors' Supply Co., of Albany, was \$25,000 in excess of alleged market quotations. During the first day's inquiry Col. Greene submitted numerous receipted vouchers for supplies, each one of which he maintained was far in excess of a reasonable market quotation.

lution to the effect that all interested railroads join in having a study made for the construction of a belt line on the west side of Bergen Hills and east of the Hackensack River for the interchange of freight.

The proposal of the railroad companies in so far as physical changes are concerned agrees substantially with the Port Authority's plan, under which it estimates that the operation of belt line No. 13 as a belt line will result in an annual saving of about \$1,100,000. The operating arrangement proposed is not complete unification as proposed by the Port Authority, but is expected to give practically the same results without the legal complications necessary to effect unification and it can be modified at any time that the Interstate Commerce Commission feels that shippers are not getting the full service they would get under unified operation.

The portion of the middle belt line No. 1 which the railroads propose to set up is practically all in existence, with the exception of four miles of extensive trackwork at the north end. Its primary function is to divert through business and interchange business away from the congested yard around the water front. The railroad companies consider it much more essential than belt line No. 13 and have been considering ways and means of building it for a number of years. The recent hearing made it possible for them to bring forward the proposition in order to discuss the details and method of construction with the Port Authority. In regard to financing the necessary improvements, the counsel for the Port Authority said that the Port Authority stands ready to use the power vested in it as a Port Authority to acquire any additional land, equipment, facilities, or anything else that may be needed for the operation of this or any other part of the Comprehensive Plan, and are prepared to borrow the money necessary to effectuate the same upon the rates of interest the tax exempt securities will bear in the market; that it stands ready at any time that such action becomes desirable to become the operating agency of either belt line No. 13 or any other part of the Comprehensive Plan.

Ramapo Water Project of City of Bayonne Upset

The New Jersey Court of Errors and Appeals has ruled that the City of Bayonne cannot take water from the Ramapo River for its supply because it failed to get the consent of the North Jersey District Water Supply Commission before applying to the State Board of Conservation and Development for a water right permit. In addition, the court holds the permit from the Conservation Board to be of no force because of certain technical defects in the proceedings. The Bayonne application was filed in 1921, and the permit was granted on March 23, 1922 (see *Engineering News-Record*, March 30, 1922, p. 511). The permit allowed Bayonne to divert 50 m.g.d. from the Ramapo River and continued various requirements as to supplying water to other communities and developing a larger supply, if demanded.

Some of the opponents of the Bayonne project held that notwithstanding the provisions to safeguard other communities inserted in the permit by the Conservation Board the grant violated that water policy of the State as embodied in legislation creating the North Jersey Water Supply District and providing that no municipality in the district should be allowed to acquire rights in any new source of water supply without the approval of the District Commission.

Bayonne maintained (1) that certain home rule legislation enacted after the district was created freed it from the jurisdiction of the District Board and (2) that since it now gets water from the Passaic River (by contract) and since the Ramapo is a "branch" of the Passaic therefore the Ramapo would not be a new source of supply. The State Supreme Court upheld contention (1) but the Court of Errors and Appeals reversed that decision and disallowed (2) as well. As to the second point, the highest court held that a "branch" is a part of a parent stream while a tributary has a drainage area of its own until it discharges into some other stream or body of water, after which the waters of the tributary become a part of the stream so joined. Consequently, the Ramapo River would be a new source of supply for Bayonne.

The suit in question was brought by the Borough of Oakland and other municipalities in the Ramapo drainage area. Since the city authorities of Bayonne voted to take steps to get a water supply from the Ramapo, there has been a city election which resulted in a majority of the City Commission or Council adverse to the Ramapo project.

To Raise Endowment for Stevens Institute

The Stevens Institute of Technology million dollar endowment campaign was given impetus at a meeting held Sept. 27 at the Engineers' Club under the direction of John W. Lieb, vice-president of the New York Edison Co., who is in charge of the campaign in Manhattan, New York City. Plans for raising the New York quota for the fund were perfected following an address by Alfred R. Whitney, Jr., of the Whitney Co., who is a member of the national executive committee for the fund.

A. P. Davis Made Chief Engineer of East Bay District

Arthur P. Davis, late director U. S. Reclamation Service, has been appointed chief engineer, and Gen. George W. Goethals, of New York City, and William Mulholland, of Los Angeles, consulting engineers, of the East Bay Municipal Utility District, comprising municipalities across the bay from San Francisco. The first objective of the district is to purchase the existing privately owned water-works serving that territory, and the next is to construct additional supply works. As sources of supply there have been suggested for choice the Sacramento, McCloud, Yuba, American, and Eel Rivers; also partnership with San Francisco in the Hetch Hetchy supply.

At a meeting of the directors of the district on Sept. 20, it was voted to have Mr. Davis report on whether a lack of water or its improper distribution contributed to the great fire in Berkeley on Sept. 17.

Bids Rejected for Perth Amboy Raritan River Bridge

The New Jersey State Highway Commission has rejected all the bids for the new bridge over the Raritan River at Perth Amboy as being too high. The lowest bid was about \$600,000 in excess of the highway department's estimate; it was the bid of the Frederick Snare Corp. of New York for a total of \$3,934,000. The same corporation submitted a bid of \$3,890,000 for the bridge without trolley tracks or power conveyors and of \$3,872,000, omitting asphalt block pavement. Other bids submitted on a similar basis were The Stillman, Delahanty Ferris Co. of Jersey City, \$4,444,696 and \$4,329,696; and Patrick McGovern, Inc., New York, \$4,933,011 and \$4,793,011. It is expected that the bids will be re-advertised some time in December and it is possible that the designing engineer, Clarence W. Hudson, will suggest some changes to be made in the design in order to bring the cost more nearly to the amount of the original estimate.

Voters Approve Philadelphia Transit Plans

Approval was given on Sept. 18, at the time of the primary elections in Philadelphia, to a transit referendum bill transferring previously appropriated funds from the purposes for which they had been voted, to construction of subway lines in accordance with the plans recently approved by City Council. The referendum was carried by a majority of 151,500 votes. It releases about \$48,000,000.

The funds had formerly been "earmarked" for certain lines, but they were not sufficient in any case to complete the lines contemplated. The transfer approved last week makes the money available for Step No. 1 in the comprehensive transit plans recently developed by a Councilmanic Transit Commission, as described in *Engineering News-Record*, Aug. 2, 1923, p. 196.

As the funds thus made available will not be sufficient to complete the work of Step No. 1, additional funds are expected to be included in a new loan bill to be voted on in November.

Calendar

Annual Meetings

AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 8-11.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 17-20.

AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga., Nov. 12-16.

CITY MANAGERS ASSOCIATION, Lawrence, Kansas; Annual Meeting, Washington, D. C., Nov. 13-15.

AMERICAN ROADBUILDERS' ASSOCIATION, New York City; Annual Convention, Chicago, Jan. 11-18.

American Water Works Association, New York Section, will hold its first meeting for 1923-4 at Watertown, N. Y., Saturday, Oct. 6.

The Engineers' Society of St. Paul will celebrate on Oct. 8 the fortieth anniversary of its founding. Charles F. Loweth, president of the American Society of Civil Engineers and a charter member of the St. Paul society, will give the principal address. The first meeting of the fall season, Sept. 10, was addressed by Col. Frederick Mears, chief engineer of the St. Paul Union Depot Co., on "Alaska Railways," of which he was formerly chief engineer. On the same day the society resumed its bi-monthly luncheons, being addressed by B. M. Cowan and W. F. Brown, chief engineer and assistant chief, respectively, of the new Ford plant at St. Paul.

Personal Notes

JAMES H. FUERTES has been retained by the Board of Water Commissioners of Denver, Colo., to act in an advisory capacity and to assist the engineers of the board in preparing plans and specifications for the city water improvement under the \$6,500,000 water bond issue authorized in the last city election.

C. A. BAUGHMAN, who spent the summer with the Iowa State Highway Commission investigating the comparative value of concrete pavements of various kinds in order to aid in preparing specifications for hard-surface roads, has now returned to his work as professor of highway engineering in Alabama Polytechnic Institute, Auburn, Ala.

SAMUEL REA, president of the Pennsylvania R. R., celebrated on Sept. 21 the 52nd anniversary of his connection with the railroad, his services having started in the position of chairman. He has been president of the lines since 1912.

CLYDE A. WALB, whose term as vice-chairman of the Indiana board for the registration of professional engineers and land surveyors will end about the first of next year, has resigned.

HON. FRANK OLIVER, of Edmonton, Alta., formerly Canadian Minister of the Interior, has been appointed a member of the Dominion Board of Railway Commissioners, succeeding the late Dr. James G. Rutherford.

GEORGE GUY, former engineer of the public utilities commission of Winnipeg, has been made managing director of the Tudhope-Anderson Co. of Onillia, Ont.

H. G. BAYLES, Morgantown, W. Va., has been chosen city manager, succeeding Arthur A. Hall, resigned, who returns to his former employment as professor of electrical engineering at West Virginia University, Morgantown.

THE MCKELVEY CONSTRUCTION CO., St. Louis, Mo., has opened a branch office at 320 St. Charles St., New Orleans, La., with B. H. Alvey in charge. Recently this company opened a branch in Detroit.

C. L. HUGGINS, city engineer of Berkeley, Calif., has tendered his resignation, effective Oct. 1.

R. P. KITE, of the Dorr Co., engineers, has been transferred from the New York office to the Chicago branch, where he will work with J. V. Slade.

L. E. ANDREWS has been appointed division construction engineer with the New Jersey State Highway Commission, in charge of the Northern Division, with headquarters in Newark. Mr. Andrews was formerly survey engineer in the Southern Division, and previous to that was assistant district engineer with the Pennsylvania State Highway Department; engineer officer on road construction in France and resident engineer with the Illinois State Highway Department.

C. A. BURN, of Caldwell, N. J., will have direct supervision of highway construction in New Jersey for the Public Service Production Co., of Newark. Mr. Burn was formerly Northern Division construction engineer with the New Jersey State Highway Commission.

V. BERNARD SIEMS, who has been assistant water engineer at Baltimore, Md., has been appointed water engineer. Re-appointments, also, are: STEUART PURCELL, chief engineer; BERNARD L. CROZIER, highways engineer; and BANCROFT HILL, harbor engineer.

COL. WILLIAM KELLY, the chief engineer of the Federal Power Commission, is making a detailed inspection trip throughout the Rocky Mountain region. He expects to visit a considerable number of projects. During Col. Kelly's absence, Major H. S. Bennion will act as chief engineer for the commission.

ED. O. McMAHON, formerly assistant engineer with Howard McCurdy, Los Angeles, Calif., is now located at Santa Ana, Calif., in charge of field work for Hoy & McMahon, civil engineers.

L. J. FELLOWS, formerly assistant engineer for the Longbell Lumber Co. on street paving at Longview, Wash., is now engineer in charge of construction of a power plant at Longview, for Charles C. Moore & Co., engineers.

COL. CHARLES KELLER, of the Corps of Engineers, has been retired from active duty in the Army after more than thirty-seven years of service. The action was taken at the request of Col. Keller. It means that Col. Keller has definitely cast his lot with the hydro-electric industry. Col. Keller was made manager of the El Dorado project being developed by the Western States Gas & Electric Co. in the Sierras near Placerville, Calif. He was granted a leave of absence in April, when he resigned as engineer commissioner of the District of Columbia.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Time Saved for Buyer of Supplies by Organized Sales Methods

Assignment and Follow-Up of Prospects Prevents Needless Calls
and Disputes About Commissions

By ALBERT H. RHETT
Summit, N. J.

INTERVIEWS with salesmen of construction equipment and materials are often regarded by contractors, engineers and architects responsible for purchasing or recommending the purchase of machinery and supplies, as a necessary, but onerous and time-consuming part of their duties. The selling of building supplies and contractor's plant presents some of the most difficult problems in the whole field of merchandising, yet seldom does the user of equipment consider this problem of selling from the point of view of the manufacturer. The peculiar feature about selling in the construction industry is that in almost every case two individuals with somewhat divergent interests have to be "sold." It is difficult enough to sell one thing to an individual who needs it, but more than twice as hard to sell the same thing to two individuals who do not, very often, want the same thing.

These two people are the engineer or architect and the contractor. Their divergence of interest arises from the fact that the engineer or architect, being responsible for results, desires the best he can get, while the contractor, at least on the usual lump-sum form of contract, desires—and this is said with apologies where due—the cheapest. The question of personal friendship or favoritism also enters doubly. The sales problem, therefore, is to synchronize these interests into orders on as many building and construction operations as possible.

ONE MANUFACTURER'S METHODS

It is proposed to show below the method used in the case of a manufacturer in New York City producing a varied line of specialties sold throughout the country. The method has two phases pertaining to local and national distribution, of which the local phase will be considered first. In the greater metropolitan district there are nearly a thousand architects; from 3,000 to 4,000 projects have to be followed for various materials each year. Competition is keen; prospects most difficult to see; and only the most direct and efficient sales methods will produce satisfactory results. The multi-phase nature of the sales effort to be made affects every detail of the sales management problem—assignment of work to the salesmen, method of follow up, even method of compensation.

All construction projects begin in the office of the engineer or architect and as it is desirable, if not always necessary, to have specifications that will cover the supplies or equipment to be distributed, the sales effort must begin at this point. Each project is bid

on by many contractors from various localities and one contractor may have contracts from the offices of several engineers or architects. In this fact arises the first difficulty, the method of assignment of work to the salesmen.

It would be desirable to have but one salesman of the same manufacturer call at the office of each engineer and each contractor and an attempt to do this has been made by following specially

architects in the district were arbitrarily divided among the various salesmen. Each man was allowed to call only on the offices assigned to him, and was held responsible for results or lack of results obtained on all projects emanating from these offices.

This plan produced the desirable result of having but one man call on each engineer or architect but was open to the objection that various salesmen did call on the same contractor on various projects. It was thought that this objection was more than offset by the fact that but one salesman had to familiarize himself with each project and he alone handled all the negotiations with the various parties concerned on each operation.

It might be anticipated that with several men calling at a contractor's office, poaching and commission or credit disputes would inevitably result, but this was obviated by a simple card record system which also provided an almost automatic follow-up index.

CARD RECORD SYSTEM

Advance information of all proposed operations was received from one of the agencies providing this service.

NO	PROJECT	DATE	SALESMAN	ARCHITECT	CONTRACTOR	SPEC.	QUOTATION	SALES	CALLS
4151	Office Building 16 stories & basement 8th Ave. & 47th St. Brick, Steel Frm. fl. \$3,000,000.-	7-15	Sharp	McBride & White	Miller & Johnson				7/17 8/3 8/5, 8/7 9/1

trained salaried men do the preliminary work in the engineer's office and commission salesmen do the actual selling in the contractor's office. The inevitable result, however, is loss of continuity, duplication of effort and credit disputes. A territorial method of assignment is also, obviously, out of the question, because the engineer or architect may be located in one district, the contractor in another, the job in another, the owner in another—and all may have to be followed up.

PLAN OF ASSIGNMENT

In the instance under consideration the plan of assignment used was based on the theory that the sales effort must begin with the engineer or architect at the specification stage and the man beginning it is the man to follow it through to its consummation. Consequently, the offices of all engineers and

Each project was serially numbered, entered on the card (Fig. 1) and referred to the salesman to whom the office of the architect or engineer concerned had been previously assigned and on whom he was expected to call promptly in regard to this specific job. All salesmen made daily reports, referring to each job by serial number. The dates of calls were entered in the right hand column; quotations or sales also were recorded. All orders, however received, were traced to the operation on which they were used and if the record showed that the salesman to whom the operation had originally been referred had properly followed it, his credit was immediately established. On the other hand, if the record showed neglect, he received no credit.

The follow-up was effected by surveying the call column periodically and notifying the salesman involved if any

job failed to show a call date within a reasonable period. It will be observed that each job, when entered on the Prospect Record (Fig. 1), was simply given a serial number and it was necessary to index these numbers with two supplemental index cards, (1) a location card for each job (Fig. 2) filed according to location and giving the serial number, and (2) a card for each architect's office (Fig. 3) filed according to name of architect and giving description and serial numbers of current work in that office.

REASONS FOR INDEXING

There are several reasons for this indexing. If a salesman picked up a job on the outside he was required to register it and get a serial number for it. With the location or architect's name known it could be seen at once from the respective cards whether or not it had been previously assigned or worked, and conflicts and duplication of effort thus are avoided. Conflicts and duplication were also likely to arise from the assignment to the wrong man of the "follow up" on telephone requests for quotations or information on any operation. If the inquirer could give the location of the job or architect's name the serial number could be ascertained from either index card and this reference number on the main card gave the full history of the job and the man working it. It was also desirable to have a complete record of all work in each architect's office. The keeping of this simple three-card system insured the following of every possible prospect, increased the volume of sales and absolutely eliminated credit disputes among the salesmen.

Another factor that had an important bearing on the situation was the method of remuneration of the salesmen. It was found that the salaried men worked the architect's offices very nicely but were not always "there" when it came to the final struggle of closing in the contractor's office. On the other hand, the commission men were always looking for the quick break in the contractor's office and would not do the time-consuming, but essential, work in the offices of the engineers or architects. The salary plus commission method of payment was found to give the most satisfactory results.

NATIONAL DISTRIBUTION

When the question of national distribution is considered matters become still more complicated. Of course if district offices are used the same system could be applied in each office, but only the larger cities can support a district office and there is considerable expense to be carried in the way of office, storage and trucking facilities. There is, however, in almost every town of any size a building supply dealer with these facilities and as the market for the commodities manufactured in this instance was general, this method of distribution was used.

The objection, however, is the same as that encountered in the use of commission men on the local work. The building supply dealer sells the contractor and is usually neither inclined nor equipped to do much work with the architect or engineer. This necessary part of the work had to be otherwise accomplished by dividing the dealers into groups or districts and having a salaried man from the home office cover

August Paving Brick Shipments

Paving brick shipments for the month of August were higher than for any previous month in 1923, according to statistics just issued by the National Paving Brick Manufacturers Association. Reports from 67 per cent of the industry's tonnage showed that shipments were more than 9,000,000 greater for August than for July, 36,446,000 brick being shipped in August and 27,092,000 in July.

Production for August was 33,457,000 brick as against 30,529,000 for July. Stock on hand the last day of August was 74,399,000 as against 78,835,000 the last day of July. This reduction of 4,000,000 in stock on hand was due to the heavy August shipments.

There was a falling off in unfilled orders amounting to 12,000,000 brick, a natural trend toward the end of the summer paving season.

Ohio led all other states in consumption, 5,781,000 brick going for city streets and 5,784,000 for country highways. Illinois was second with Pennsylvania, Nebraska and Texas following closely.

Form Cinder Concrete Association

The National Cinder Concrete Products Association was formed in Philadelphia recently by manufacturers of the Straub patented cinder concrete building block. The purpose of the Association is to increase the use of cinder concrete products and to engage in research work for the improvement of methods of manufacture.

Francis J. Straub, of New Kensington, Pa., was elected president. The other officers are: first vice-president, Raymond M. Weeks, Philadelphia; second vice-president, Henry Boettcher, Lancaster, Pa.; secretary, J. Edwin Rutter, (Cameron and Reilly Sts.), Harrisburg, Pa.; treasurer G. Edgar Allen, New York.

Only corporations and individuals holding licenses from Crozier-Straub, Inc., New York, are eligible for membership.

all the architects and engineers in each district periodically, working with the dealer and selling through him.

This work was given point and intensity through the use of a card record (Fig. 4) somewhat similar to that used locally. This form of card was kept for each dealer. Advance information of the most important projects in each district was obtained from an available source and entered on this card and on two additional copies. One copy went to the dealer with the request that he fill in the information and return. Sometimes he did this and sometimes he did not, but it acted as a prod or reminder. The second copy went to the salesman who covered that district, so that he went to each locality with advance information, at least on the major projects, and did not have to rely on the dealer for information. He reported by number the result of his work on each job and this was entered on the original card. This record was of further use in showing to which dealer should be referred requests for information received through the mail and also in straightening out disputes between dealers which most often arose through the complication of the architect being in one location and the contractor or job in another.

Business Notes

L. W. KEMP, superintendent of the Southwest division asphalt sales department Texas Co. at Houston, Texas, has been appointed manager of the Texas Rock Asphalt Co., San Antonio. Mr. Kemp is a graduate of the University of Texas. He is succeeded by Col. A. D. Stivers, formerly the Texas Co.'s representative in Dallas.

HENRY SEIBEL, president of the Seibel Air Spring Co., San Francisco, manufacturer of shock-absorbing seats for industrial and farming equipment and motor trucks, was the guest of honor at a dinner tendered him by friends on the occasion of his seventieth birthday, Aug. 29, at the Hotel Whitcomb, San Francisco. Col. Charles A. Simmons, manager of the local Chamber of Commerce was toastmaster.

Equipment and Materials

New Shank and Bit Punch

For punching holes when shanking and biting hollow drill steel ranging in diameter from 3 to 14 in., the Ingersoll-Rand Co., New York, has developed a new type of machine known as the "IRLP" shank and bit punch. It is made in two models, one constituting a part of the company's sharpener and the other a separate unit. The attached-to-sharpener pattern can be attached to the No. 4, 5 and 50 sharpener. The pedestal pattern is a self-contained

DRILL SHARPENER WITH SHANK AND BIT PUNCH ATTACHMENT AT RIGHT machine with pneumatic clamp, mounted on its own substantial cast-iron pedestal base.

The entire punch is under single-lever control. By holding this hand lever forward compressed air is admitted to a hammer cylinder and by a series of rapid blows the hammer cylinder with punching pin attached is moved forward, thus punching a hole in the drill steel shank or bit which is held in position by a clamping device. To remove the pin from the drill steel it is only necessary to release the hand lever. Springs attached to this lever return it to its normal position, whereby air is admitted to the opposite end of the

hammer cylinder and the pin is withdrawn by a series of hammer blows. The centering device assures holes which are centrally located and, according to the manufacturer, eliminates the chief cause for breaking water tubes.

The clamping of the steel for the attached-to-sharpener pattern is done by the sharpener crosshead; with the IR-50 sharpener the clamping pressure is 14½ tons at the 100 lb. air pressure. In the pedestal type the clamping jaws are operated through a toggle arrangement and the clamping pressure is much greater than will ever be required.

The attached-to-sharpener pattern weighs 227 lb. No extra floor space is needed for this type. The pedestal type weighs 610 lb. and requires a floor space of 2½ x 4½ ft.

Saw Frame Attachment for Tractor

For attachment to a Fordson tractor, the Stover Manufacturing & Engine Co., Freeport, Ill., has placed on the market a saw frame. Except for the sawing table, the frame is of all-steel construction. Angle steel braces carry-

ing the table extend low enough to rest on the ground, making a stiff support. The distance from the center of the saw mandrel to the ground is 30 in. The drive is by belt from the tractor engine and the frame has an adjusting bolt each side to take up slack in belt.

The frame is carried on four castings attached to the upper and lower ends of the radiator by four bolts that run in front of and in back of the radiator, as shown in the accompanying illustration. The frame, therefore, may be attached without disturbing any bolts or nuts on the tractor and also without drilling any special holes. The circular saw has a diameter of 30 in. The shipping weight of the frame, knocked down, is 250 lb.

Publications from the Construction Industry

Centrifugal Pumps—ERIE PUMP & ENGINE CO., Medina, N. Y., describes in a 23-p. illustrated bulletin its double-suction, horizontally split shell centrifugal pumps for water-works and industrial service, including the handling of ammonia water, brine and hot water. The pumps are built in a variety of sizes with discharge diameters from 2 to 20 in. and capacities of 150 to 14,000 gal. per minute. For handling brine an all-iron type of design is employed, while for service with chemicals pump casings are furnished in acid-resisting bronze.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 187 to 200, are the following:

Loft, New York, N. Y., Rathmuk Realty Co., \$2,500,000.

Apartment, New York, N. Y., A. Campagna, \$5,000,000.

Recent Unit-Bids Throughout the Country

Unit prices of various materials and operations, applying on several of the more important contracts recently awarded, are compared in the accompanying table. Materials and operations, though very similar in nature, show diversity of unit costs according to geographical location. For instance, 3 mi. of concrete paving cost \$28,333 per mi. in Tulsa, Okla., as against 1 mi. of concrete highway in the state of Washington at \$42,583. Excavation of 2,780,000 cu.yd. of navigation channel at Lake Charles, La., cost 13.8c. per cu.yd., compared with 8,700 cu.yd. of channel excavation at Anamosa, Ia., at 48c. per cu.yd. Seventeen miles of gravel surfacing at Lake Village, Ark., cost \$6,470.59 per mi., against 9 mi. of Louisiana state highway at \$5,269.45 per mi. and 11.6 mi. in the state of Washington, at \$4,994.22 per mi.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 187 to 200, are the following:

Power Plant, Florence, Ala., to Alabama Power Co., Birmingham, Ala. \$3,472,487.

Bank and Office, Pasadena, Calif., to Scofield Eng. Co., Los Angeles, \$1,000,000.

High School, New York City, to Willets Constr. Co., \$2,057,000.

Bank, Seattle, Wash., to Puget Sound Bridge & Dredging Co., \$1,250,000.

Temple, Springfield, Mass., to A. E. Stephens Co., \$1,000,000.

Next week—"Brick and Cement Imports Not Large but Increasing."

A tabulation of fifty large contracts awarded this year is being prepared for early publication in this section.

Freight Loadings at New High Mark

More cars were loaded with revenue freight during the week which ended on Sept. 1 than during any week heretofore in history. The total for the week, 1,092,567 cars. This exceeded by 22,635 cars the previous record, which was established during the week ended Aug. 25 this year, when 1,069,932 cars were loaded.

Value of September Contracts 24 Per Cent Heavier Than For Same Month Last Year

Total of 708 Awards During September, Average Value \$244,452,
Compared With 820 in August, Averaging \$172,681

The total value of contracts awarded on large engineering construction projects, in the four September issues of *Engineering News-Record*, reached \$173,072,000 as compared with \$141,599,000 in the five issues of August. This represents an average weekly value of \$43,268,000 for September, against \$28,319,800 during the preceding month.

The weekly average of \$43,268,000 for the month of September represents an increase in money value of nearly 26 per cent above the weekly average for the corresponding period in 1922.

September, 1922, contracts totaled \$138,648,000.

Minimum costs observed in Construction News on each class of construction are as follows: Water-works, \$15,000; other public works, \$25,000; industrial construction, \$40,000 and commercial buildings, \$150,000.

Of the \$173,072,000, a total of \$6,132,000 represented Canadian awards, which fell off heavily from August.

Streets and roads gained 6 per cent in total money value during the month, while buildings increased 33 per cent and excavations, 50 per cent. September

totals for bridge construction and miscellaneous work, tripled those for the month preceding. Water-works, sewers, industrial construction and Federal Government work fell off somewhat during September.

Among the large projects awarded during September were the following: The Moffat tunnel project in Colorado, \$6,075,000; sewage treatment works, Chicago, Ill., \$5,602,636; a nineteen story office building in Dallas, Tex., \$5,500,000; bridge over the Carquinez Straits, \$4,500,000; a 260 ft. dam at Danville, Ky., \$4,000,000; and a hospital at Cleveland, O., \$3,300,000.

The actual physical volume of construction represented by September contracts is 6 per cent greater than September, 1922; 50 per cent heavier than for the corresponding period in 1921 and twice the volume of September, 1920, lettings.

Engineering News-Record Construction Cost Index Number

October, 1923	220.30
September, 1923	221.50
October, 1922	188.60
Peak, June, 1920	273.80
1913	100.00

Engineering News-Record's Construction Cost Index Number declined 1.2 points since last month, owing to drop in lumber. Prices of other basic building materials remained unchanged during the month. The average rate for common labor is still 54c. Thus, general construction cost is 17 per cent higher than one year ago and 20 per cent under the peak; it is 120 per cent above the 1913 level.

Engineering News-Record Construction Volume Index Number

Monthly	
September, 1923 (4 issues of E. N.-R.)....	137
August, 1923 (5 issues of E. N.-R.)....	111
September, 1922 (4 issues of E. N.-R.)....	129
1913	100
Yearly	
1922 (entire year).....	130
1921 (entire year)	88
1920 (entire year)	91
1913	100

Engineering News-Record's Construction Volume Index Number is 137 for the month of September, and 130 for the whole of 1922, as against 100 for 1913. This means that the actual volume of construction in 1922 (not the mere money-value of the contracts let that year) is 30 per cent above the volume of construction for 1913. Our monthly volume number, 137 for September, 1923, is really the increment of construction, and indicates the rate at which contracts are being let as compared with 1913 awards.

VALUE OF CONTRACTS LET IN THE UNITED STATES AND CANADA DURING SEPTEMBER, 1923

	New England	Middle Atlantic	Southern	Middle West	West of Mississippi	Western	United States	Canada	Total

Labor Rates and Conditions Throughout the Country

Fewer wage changes and a slight decrease in employment mark the industrial situation at the beginning of the autumn season.

Twenty-three wage changes were noted by the National Industrial Conference Board for the month ending Sept. 15, against seventy-seven during the preceding month. Of the twenty-three, twenty-two were increases and one a decrease.

Latest reports of the U. S. Department of Labor show a decrease in employment of only 0.45 per cent in one month.

Tremendous building programs continue in nearly all of the principal centers throughout the country. State and county highway construction is particularly active with a shortage of labor reported in some sections.

The average rate paid common laborers, pick and shovel men in construction operations, remains at 54c., the same as for July, August and September as against 53c. per hr. during June, according to *Engineering News-Record* figures. Local building conditions are as follows:

Baltimore—Scarcity of structural

iron workers. Conditions nearing normal among hod carriers and common laborers; normal in other crafts.

Boston—Bricklayers scarce; other trades plentiful. Minimum carpenters' rate, \$1, maximum, \$1.10, against \$1.05 per hr., last month.

Dallas—Excessive demand for bricklayers and carpenters; other crafts plentiful.

Denver—All building trades 100 per cent employed.

Detroit—Good supply of men for all trades available; no shortages noted.

Los Angeles—Construction active.

CURRENT BUILDING TRADES WAGE RATES PER HOUR

(Higher rates indicated by +, decreases by —)

Cities	Bricklayers	Carpenters	Hoisting Engineers	Load Carriers	Pile Drivers	Structural Iron Workers	Common Labor

St. Louis	1.50@1.75	1.50	1.25@1.37½	1.25	1.25	1.25@1.50	—45@100
San Francisco	1.25	1.00	1.00	.81½	1.00	1.12½	.50@.55
Seattle	+1.25	1.00	+1.00@1.12½	.93½	+1.00@1.12½	1.12½	+56½@.62½

Minneapolis—Labor conditions easy. Slump in building construction.

Montreal—Scarcity of structural iron workers; plenty of other building trades mechanics. Common labor rate down 5c. per hr. since last month.

New Orleans—Labor adequate to all demands.

New York—Wage conferences expected to begin during current month. Bonus agreements with many trades expire at end of the year. Bricklayers beginning to be plentiful; many accept-

ing flat rate of \$12 per day with no bonus. Scarcity of plasterers; those working six and a half days per week, with one hour overtime per day, receive \$122.50 per week.

Pittsburgh—Bricklayers scarce. Continued demand for common laborers.

St. Louis—Bricklayers now receiving \$1.50 will demand \$1.75, Nov. 1. Carpenters' rate \$1.50 per hr., effective Oct. 1.

San Francisco—While new work is not in sight to any appreciable degree,

there is very little unemployment among members of the local building trades councils. The disastrous fire at Berkeley which destroyed over 600 dwellings will undoubtedly tend to keep down unemployment among building trades mechanics.

Seattle—Bricklayers advanced to \$1.25 from \$1.12½ per hr. Maximum rate for hoisting engineers and pile drivers, \$1.12½, against \$1 per hr. Minimum for common laborers, 56½c., compared with 50c. per hr. last month.

Monthly Prices of Construction Materials

Ups and Downs of the Market

Pig Iron—Market weak, with prices tending downward. Iron still being piled up, despite high production cost due principally to labor. Quotations under \$23 per ton for No. 2 foundry iron have been made at Birmingham.

Railway Supplies—Minimum on light rails, \$43 at Pittsburgh mill, against \$45 per ton, one month ago. St. Louis quotations at maximum of \$43. Oak and cypress ties up 5c. in St. Louis. Standard spikes and track bolts higher in San Francisco and St. Louis. Light rail and track fastenings' markets dull, particularly in Chicago district.

Pipe—No changes in wrought steel, wrought iron or cast-iron pipe during month. Clay drain tile (New York) same price as year ago. Slight decline in sewer pipe in Baltimore. Four-inch sewer pipe advanced in New Orleans due to scarcity of that gauge.

Road and Paving Materials—Few changes in road oil and asphalt prices since last month. Baltimore reports drop of \$3 in package asphalt and \$1 per ton in bulk. Wood block firmer in Boston and New Orleans, due to increased costs of lumber, creosote oil and labor; slightly lower in Minneapolis and Atlanta.

Sand, Gravel and Crushed Stone—

Gravel down 5c. per ton in Atlanta. Both sand and gravel lower in Baltimore. Sand and gravel being stocked for winter demands. Crushed stone, 3-in., down 10c. in St. Louis and 25c. per cu.yd. in Minneapolis, during month.

Lime—Hydrated finishing, down 50c. in Philadelphia and \$2 per ton in Dallas; up 50c. in Atlanta. Hydrated common, advanced 50c. in Atlanta and 60c. in Baltimore; declined 50c. per ton in Philadelphia. Lump finishing, dropped 20c. in Boston and rose 5c. per bbl. in Atlanta. Common lump down 69c. in Philadelphia and 60c. per bbl. in Dallas, due to increased output of Southern lime.

Cement—Stability of cement market unbroken in forty-six centers, reporting regularly to *Engineering News-Record*, excepting slight advances in Philadelphia and at Fordwick, Va., mill.

Structural Steel—New buying of plates and structurals extremely quiet. Numerous small orders, however, received for new plate tonnages. Bulk of plate tonnage for car and tank construction. New structural business firm at \$2.50 base, but mostly confined to small tonnages. Plates quoted as low as \$2.40 per 100 lb., Pittsburgh, with very small tonnages at \$2.50. Bars at

\$2.40 base; buying more active for fourth quarter requirements.

Brick and Hollow Tile—Common brick down 25c. in Detroit, \$1 in Atlanta and \$2 per M. in Boston, during month; no advance reported. Slight decline in hollow tile in New York; no advances in twenty-one cities reporting.

Lumber—Increase in yellow pine orders and inquiries for fall trade. Fir timbers advanced \$3 in San Francisco and yellow pine, declined \$2 per M. ft. in New York, during month. No changes in hemlock and spruce. Pine down 50c. to \$1 in Atlanta. Fir declined \$1 per M. ft. in Minneapolis. Pine timbers advanced \$1 in Philadelphia and \$3 in Boston. Fir timbers rose \$1 in Seattle and \$1.25 to \$2 per M. ft. in Minneapolis, due to Japanese demand.

Explosives—Slight decline in 40 per cent gelatin dynamite reported in St. Louis. Both 40 and 60 per cent advanced in Los Angeles.

Scrap—Iron and steel scrap prices weaker, particularly in Chicago district.

Linseed Oil—Raw oil declined 1c. per gal. f.o.b. New York, in month; dropped 2c. in Atlanta and 7c. per gal. in San Francisco.

Pine advances since last month are indicated by heavy type; declines by *stiles*.

PIG IRON—Per Gross Ton—Quotations compiled by The Matthew Addy Co.:

San Francisco and New York quote on hollow partition tile.

STRUCTURAL MATERIAL—Following are base prices f. o. b. mill, Pittsburgh and Birmingham, together with quotations—per 100 lb. from warehouses at places named:

Material	Warehouse					
	Pittsburgh	Birmingham	New York	Dallas	St. Louis	Chicago
Beams, 3 to 15 in.	\$2.50	12.75	\$3.64	\$4.20	\$3.45	\$3.40
Channels, 3 to 15 in.	2.50	2.75	3.64	4.20	3.45	3.40
Angles, 3 to 16 in., 1 in. thick	2.50	2.75	3.64	4.20	3.45	3.40
Tees, 3 in. and larger	2.50	2.75	3.64	4.20	3.45	3.40
Plates, 1 in. thick and heavier	2.50	2.75	3.64	4.20	3.45	3.40

RIVETS—The following quotations are per 100 lb.:

Material	STRUCTURAL					
	Pittsburgh	New York	Chicago	St. Louis	San Francisco	Dallas
1 in. and larger	\$3.00@3.25	\$4.40	\$3.85	\$3.75	\$4.15	\$5.00

Material	CONE HEAD ROLLER					
	Pittsburgh	New York	Chicago	St. Louis	San Francisco	Dallas
1 in. and larger	\$3.10@3.35	\$4.50	\$3.95	\$3.85	\$4.35	\$5.10
1 and 1 1/2	3.25@3.50	4.66	4.11	4.00	4.70@4.95	5.25
1 and 1 1/2	3.50@3.75	4.90	4.35	4.25	4.95@5.10	5.50

Lengths greater than 1 in. take an extra of 50c. Lengths between 1 in. and 2 in. take an extra of 25c.

NAILS—The following quotations are per keg from warehouse:

Material	Warehouse					
	Pittsburgh	New York	Chicago	St. Louis	San Francisco	Montreal
Wire	\$3.00	\$3.80	\$4.25	\$4.25	\$3.34	\$4.95
Cut	4.45	5.80	5.75	3.64	5.00

SHIP SPIKES—Current prices per 100 lb.:

In.	Warehouse			
	Pittsburgh	New York	Chicago	St. Louis
1 in.
1 1/2 in.
2 in.

Pittsburgh base in lots of 200 kegs or more, \$3.50.

PREPARED ROOFINGS—Slate-surfaced roofing (red and green) in rolls of 108 sq.ft. costs \$2.50 per roll in less than carload lots f.o.b. Philadelphia.

Single shingles, red and green slate finish, cost \$5.75 per square (sufficient to cover 100 sq.ft.) in less than carload lots, f.o.b. Philadelphia. Strip shingles (4 in 1) f.o.b. Philadelphia, L.L., \$5.55 per square.

ROOFING MATERIALS—Prices f.o.b. New York, in less than carload lots:

Tar felt (14 lb. per square of 100 sq.ft.) per ton	\$67.50
Tar pitch (in 400-lb. bbl.) per 100 lb.	1.62
Asphalt roofing (in barrels), per ton, f.o.b. plant*	38.75
Asphalt felt (light), per ton, f.o.b. plant*	75.00
Asphalt felt (heavy), per ton, f.o.b. plant*	75.00

* Delivered in Metropolitan Dist., \$3.00 additional.

WINDOW GLASS—Double strength, box list, united inches, 34, "AA" grade, at discount of 84@85 per cent from standard lists, f.o.b. New York; "A" grade less 86@87 per cent and "B" grade, 88@89 per cent.

SHEETS—Quotations are per 100 lb. in various cities from warehouse also the base quotations from mill:

NEW YORK, OCTOBER 11, 1923

Number 15

Why Not a Cement Committee?

THERE is no doubt that there is a growing feeling among engineers that we do not know enough about the real nature of portland cement. It is an obscure material, of complicated composition and with curious reactions, affected acutely by processes of manufacture. It is in recognition of this feeling that the cement manufacturers, as announced by one of their number at the last meeting of the American Society for Testing Materials, have initiated a study into the nature of their product. More should be done. It seems an excellent time for the American Society of Civil Engineers to revivify its committee on cement, which long ago initiated the movement for cement specifications. It is true that the subject of cement is taken care of by the Testing Materials committee, but whether that committee intends it or not it seems to be bound too close to the existing specification which it sponsored to get a true perspective on present cement needs. A new committee of the Civil Engineers, starting on the subject afresh, should achieve some useful results to supplement what the manufacturers do.

Water-Waste Prevention in Chicago Started

JUST how much credit the Western Society of Engineers can take to itself for the latest move in Chicago toward water-waste prevention is problematical. The campaign of the society's public affairs committee for waste curtailment was kindly received when the present administration went into office and much direct praise has come from the mayor. Anyway, a start has been made. The finance committee of the City Council has recommended the transfer of \$187,000 from funds set aside for a new pumping station for the installation of meters in large apartment and industrial buildings. Opposition to the metering is likely when the City Council is asked to ratify the action of its finance committee but in general the committee recommendations usually prevail. Heretofore, it has been the stumbling block. Getting its approval is therefore tantamount to accomplishment. Other controversial engineering subjects in Chicago are being threshed out in the society's committees. May they have as successful issue.

Responsible Contractors

ASSURANCE of responsibility is a prerequisite to any considerable modification of specifications which place drastic restrictions on contractors. In every recent conference which contractors have held with engineers to consider contract forms this requisite has been made plain by the engineers. As a result the committee on ethics of the Associated General Contractors has set about the task of defining responsibility. It suggests as the factors involved, financial strength, experience, equipment, performance record and personal

reference. The committee probably recognizes as fully as anyone that when every factor named has been determined, the query whether a contractor is responsible has not been answered. Much less has the irresponsibility of the contractor been established. The mental attributes which establish responsibility are not told by money or plant or testimonials but all these taken with a record of past performance are as certain, and reliable an indication as the exigencies of canvassing a score of bidders permit the engineer to secure.

Exchange of Engineers

EXCHANGE of college professors between America and Europe was instituted before the war and proved helpful in many ways. A similar though less extensive intercourse between engineers on the two sides of the Atlantic was suggested some months ago by H. C. H. Shenton, president of the Institution of Sanitary Engineers. A friendly letter on this subject, by Mr. Shenton, elsewhere in this issue, tells of the kindly reception given to George W. Fuller when he appeared at a meeting of the Institution to give in London early in September an address on American sanitary engineering practice. It is to be hoped that there may be early and repeated opportunity for American engineers and engineering societies to extend like courtesies to British engineers. We do not mean to imply that such exchanges have been wholly lacking in the past but for the most part they have been incidental. More definite planning for this sort of thing is desirable. How it can best be effected is a subject for consideration by the leaders in some of our engineering societies.

Let Road Legislation Rest

STATE highway management appears to have been selected again for legislative attack. Candidates for governor in the coming elections are talking freely of how they will handle highways. The plans range from "canning" some politically intractable road official to changing the organization and policies of a whole highway department. With the people also in a hectoring mood because of high taxes, highway officials obviously need have no fear of a dull winter. Quite as obviously the situation promises no help to sound highway development. Indeed, except in the matter of improved or increased financing, a complete rest from immediate further highway legislation would seem wise. In 1922-3 the legislatures of all but four states were in session. The count of their highway activities is impressive. In nine states the lawmakers changed highway administrations; in nineteen they changed methods of financing construction or maintenance or both; in fourteen they changed motor fees and the distribution of this income, and in thirty-two they increased old or created new gasoline taxes. Add to these changes

the acts having to do with appropriations and with traffic regulation and our "road laws" of last winter number about 170 and each one requires some regearing of the highway business machine. It has taken engineers about all the year since the legislatures adjourned to adjust the business to the changes and to get going on the altered basis. Again it should be said, it would appear to be time to take a rest from highway legislation and to develop the business of improving highways.

Public Servants

CONCERN over the large number of persons now on our federal, state and city payrolls is expressed in a circular sent out by the National Industrial Conference Board of New York City. The Board says it has found that exclusive of pensioners there are 2,700,000 "public servants" on the payrolls of the country drawing about \$3,500,000,000 annually. Such figures are interesting and to a degree impressive, but they mean little without data to show what services these employees are rendering that are not useful to the people of the United States and what part of the cost of these services would be paid to private agencies of one kind or another if our federal, state and city governments did not have these men and women on their payrolls. The significant thing is not the number of public servants and their total drafts on our various public treasuries, but how much of the work they do and the wages they draw are useful; and at what reduction in numbers and in cost the useful work could be done (1) publicly and (2) privately. Is not the work done by the National Industrial Conference Board itself in collecting these and other statistics an economic charge on the people of the whole country? Are not the Board's employees, as well as those of privately-owned utilities, and of contractors engaged in city and state construction work, public servants—good servants if their work is useful and rendered measure for measure, bad otherwise?

Low Maintenance an Asset

ALL OTHER things being equal in the question of steel versus concrete bridges, does the concrete structure offer to a city any advantages that would not apply to a corporation, such as a railroad, because of the fact that the city is subject to political pressure in the allotment of maintenance funds, while the corporation is free from such influence? The theory that there is such an advantage has been advanced by a city which found it difficult to get the council to appropriate funds for painting steel bridges. To be more explicit, the city in question has jurisdiction over eight comparatively small steel bridges. The painting of these structures was repeatedly urged by the city engineer, but was put off by the city fathers from year to year until, after ten or twelve years, it became so urgent that even the politicians could ignore it no longer. At this delayed date, however, the necessary work included a thorough scraping of the structures and three coats of paint. The city has spent \$27,000 this year on these eight steel bridges and faces the expenditure of some \$16,000 more to complete the work properly—a total amount considerably in excess of what would have been required by maintenance on a regular and systematic basis. Concrete bridges in the same city, on the other hand, have required and have received practically no maintenance and have therefore made a very favorable

impression. In selecting the most suitable type of structure for a given set of conditions the engineer must give due weight to just such psychological considerations as that advanced in this case. Even in a well regulated city political parties may change, and what seems a stable policy today may be overthrown tomorrow. It may very well be that "fool proof" structures can best be entrusted to the uncertainties of political management.

Motorists Finance Roads

AMERICANS are spending about a billion dollars a year in highway improvement. To do this they are putting over the biggest accomplishment in special taxation ever recorded for public works—the motor license and the gasoline tax. The general property tax dollar is not building roads. Less than six cents of this dollar goes to highways. The general property tax is also not being increased by our growing road improvement program. Instead it was reduced last year in a number of states—generally by boosting motor car license fees or by imposing a gasoline tax. The motor vehicle is paying for good roads and not general property. This fact needs to be made plain by state road officials and by the associated motor vehicle interests. In this matter they have identical interests even though they may disagree on every other particular of the relation of the highway and the motor vehicle. It is on the plea of reducing the general property tax that the "practical" politician is urging local management of road funds and decentralized technical control of road work. To return to either of these practices in entirety would reverse all the policies which are now developing highways as state and interstate systems—which are creating the through routes essential to the motor truck and bus carrier and the automobile tourist. As their customers and members are financing the roads, this development is the particular concern of the associations of manufacturers and users of motor vehicles. They should actively uphold the hands of the federal and state departments in advancing centralized control and engineering direction of highway improvement.

From Laboratory to Field

FOR four or five years a few experts have been trying to impress on the concrete users of this country that there is a more economical and a more consistent method of proportioning concrete than the generation-old system of integral quantities. The idea, though, has been slow of acceptance and the old 1:2:4 concrete continues to be placed in by far the larger number of actual jobs. It is a hopeful sign of progress when a large railroad, such as the Big Four, undertakes the use of one of the more scientific methods of proportioning on so large a job as the Sidney Bridge described in this issue. Mr. Huntley's article was written before the full returns from the tests are available. It also will require for complete understanding a knowledge of Professor Abrams' bulletins describing his method of proportioning concrete. Nevertheless, it is sufficiently complete at the present time to make clear that the engineers of the railroad are quite satisfied with the system which they adopted, and that they are assured that the concrete produced is not only more uniform in strength, but was produced at less cost than would

have been possible under the older and somewhat simpler methods of proportioning.

It should be recalled that the other big experiment in scientific proportioning was the concrete on the Queenstown-Chippawa Canal, where the methods devised by R. B. Young of the Ontario Hydroelectric Power Commission were used. These methods and their application to the Chippawa work have been extensively described in *Engineering News-Record*. The work on that project is practically complete, and it may be interesting to note that there, too, the engineers are convinced of the efficiency of the design method of proportioning. There is quite a difference in the Abrams and the Young details, as the students of the two methods well know, but the methods are aimed at the same results, and apparently those results are equally well achieved by either method. What it is important for other engineers and contractors to realize is that these methods have now gotten beyond the laboratory stage and are now being used on extensive operations where money is important, where time is important, and where the strength of concrete is most important of all.

Departmental Reorganization a Live Issue

IN DECEMBER a new Congress meets in Washington with a different personnel from the one that adjourned last spring and under considerably different conditions. The election last November brought forward a number of new men who will come together for the first time to try to do business with a new President, at a time when political pots are boiling as they have not boiled in many years. In this confusion of politics it may seem that the obvious necessities of government will be subordinated to the expediences of bloc or party, but, on the other hand, the fact that so many new elements have entered into the legislative mechanism may lead to a striking out into paths which the more hidebound of the veterans in Congress have hitherto been reluctant to tread. For that reason, it behooves the engineers of the country to lay their plans now for the presentation to Congress of the necessity for departmental reorganization at Washington.

There is no need here to recite the long history of the campaign to render more efficient the work of the government by the proper alignment of the various functions of government. It will be remembered, however, that at the initiation of President Harding a committee, known as the Brown Committee, presented to the last Congress a scheme for departmental reorganization which involved the re-assignment of various bureaus in a more orderly arrangement, but which was most important because it collected all government engineering under one head, the Department of the Interior, with a subordinate to the Secretary of the Interior who should have engineering qualifications and who would be in complete charge of the engineering activities of the department, which means the engineering activities of the federal government.

The necessity for some such arrangement is quite obvious; it has, in fact, been quite obvious for many years, but the recent performance of the Secretary of the Interior in summarily removing Arthur P. Davis from the direction of the Reclamation Service brought forcibly to realization the dangerous possibilities of the present political control of the scientific branches of

the government. So long as a man like Herbert Hoover is a cabinet officer or, to get outside the engineering profession, so long as a man such as James R. Garfield was a cabinet officer, there was small chance that the strictly engineering activities of a government department would be made subordinate to the needs of some chance politician out of a job. But when a political accident happens to come to power and when the exigencies of political control become so forceful as they apparently are in the Far West today, the danger of the present organization of the government department becomes apparent.

Some system of organization must be provided whereby the head of an engineering department will be by law required to be an engineer, as a general in the army must be a soldier by profession, and as the head of the Bureau of Mines must be a qualified engineer or geologist. No political superior should be empowered to juggle the law so as to take from that engineering head the responsibilities that should be his. It should be possible, of course, to remove individuals; it should not be possible to substitute so-called business men or administrators for trained engineers.

The Brown departmental reorganization may not be the best method whereby this end can be achieved, but it has the merit of the adoption by an expert committee after long study and at least stands a better chance of passing in Congress than some unauthorized scheme gotten up on the spur of the moment. Engineering societies would do well to study the main features of the Brown plan and to advise, through their local chapters, their respective congressmen of the necessities of the situation. The coming Congress will no doubt take up the Reclamation Service scandal as a specific matter, and there is a strong probability that the proper engineering control of this engineering body will be forced on a reluctant Secretary of the Interior. The attention of each congressman should be called to this possibility, but the general situation in Washington should not be overlooked. If one Secretary of the Interior can remove an engineer who has for forty years been in the service and take out of engineering control an efficient engineering bureau of twenty-one years' standing, there is nothing to prevent some other secretary from putting a country lawyer at the head of the Geological Survey or an Oklahoma gunman at the head of the Bureau of Standards. This possibility must be removed by guaranteeing at the head of the government engineering bureaus some single individual whose qualifications by law are such that whatever his personal disabilities may be, he would appreciate the necessity for the engineering direction of engineering work.

The engineers of the country might well ask Congress for some such legislation, not with any selfish purpose but with full knowledge that the government service will suffer under a political control. Group action of the engineers through their major societies and through the Federated American Engineering Societies will be useful but the most useful service can be performed by each local society or chapter with its single congressman. There is not a member of Congress who does not number among his constituents some organized groups of engineers whose opinions he is bound to consider. By making this an aggregation of local issues it can be made a paramount national issue. Persuade your Congressman and Congress itself will be persuaded.

Strength Specifications Used for Large Concrete Bridge

Abrams Method of Proportioning Concrete Used on the C.C.C. & St. L. Ry. Bridge Over the Great Miami River at Sidney, Ohio—Both Premixed and Separate Aggregates Used

By J. B. HUNTLEY

Engineer of Bridges and Structures, C. C. C. & St. L. Ry.,
Cincinnati, Ohio

THE adoption of a concrete arch, ballasted deck bridge for the new double-track crossing of the Great Miami River at Sidney, Ohio, by the C. C. C. & St. L. Ry. is indicative of the present tendency in railroad bridge design, particularly when, as in this case, the bridge is within the limits of a city. This new bridge is on a relocated portion of the railroad where existing structures do not limit the design and where

FIG. 1—VIEW SHOWING LOCATION OF CONSTRUCTION PLANT

rock foundations make it possible, without excessive cost, to use fairly long span arches. Some features of the design are notable and are given below but the principal interest in this bridge is centered in the construction methods, particularly the method of proportioning concrete.

Design—The structure, as finally designed, consists of three 140-ft. spans over the river channel and the highway, and one 100-ft. approach span on each end to take the embankment slopes, making the overall length of the structure 780 ft. The height from base of rail to bed of stream is 95 ft. The track will be carried on a ballasted deck which is supported on spandrel arches having a span of 9 ft. 9 in., the top of the parapets being 3 ft. above the rail. The piers are 17 ft. thick at the springing line, with a moderate batter, but piers 1 and 4 are widened near the base to provide for the unbalanced load between the 140-ft. and 100-ft. spans. The footing courses are carried about 2 ft into the rock, which is a peculiar form of limestone, unstratified, very hard and at least 35 ft. thick, as shown by the deepest test hole. The piers are extended

for buttresses, and above the haunches of the arch are hollow. Expansion joints in the floor and parapets are provided at the ends of each span.

The structure was designed for E70 loading, using equivalent uniform loads. This uniform load, considering half of the span loaded, was 10,400 and 10,900 lb. per foot of track for the 140 and 100-ft. spans respectively, and considering the entire span loaded, 8,500 and 8,600 lb. per ft. of track. Specifications impact was used, the impact percentage of the live-load being about 55 per cent for the 140-ft. spans and 68 per cent for the 100-ft. spans.

The 140-ft. arches are three-centered, having a rise of 50 ft.; the thickness is 5 ft. 6 in. at crown and 13 ft. 9 in. at haunches. The 100-ft. spans are semi-circular, and have thicknesses of 4 ft. 6 in. at crown and 10 ft. 9 in. at haunches. There is no tension developed at any section under live and dead-load, but temperature reinforcement was provided at the intrados and extrados, consisting of 1½-in. square bars 12 in. on centers in the 140-ft. spans and 1-in. square bars in the 100-ft. spans.

Stresses due to a rise of 50 deg. and fall of 30 deg. in temperature, combined with live and dead-load and the effect of rib shortening, were found to be quite large. The intensity of stress at some of the critical sections of the 140-ft. spans is shown in the subjoined table.

DEAD-LOAD AND LIVE-LOAD STRESSES — 140-FT. SPAN

Section	Live-Load on Entire Span				Live-Load on Half Span			
	Total		Per Cent of LL+I		Total		Per Cent of LL+I	
	D.L.	+ I	D.L.	+ I	D.L.	+ I	D.L.	+ I
Crown...	375	290	85	23	340	290	50	15
2 point...	340	250	80	24	455	290	165	36
Haunch...	200	170	30	15	270	170	100	37

TEMPERATURE STRESSES COMBINED WITH DEAD-LOAD, AND LIVE-LOAD ON HALF SPAN — 140-FT. SPAN

Section	For Rise of 50° in Temp.		For Fall of 30° in Temp.	
	Concrete	Steel	Concrete	Steel
Crown...	+675	0	+760	— 5,500
15 ft. from skew back...	+700	— 5,200	+200	— 10,500
At skew back...				

The maximum pier reaction is 25,000,000 lb., giving an average pressure on the foundation of 10 tons per square foot. The maximum toe pressure at piers 2 and 4 under unbalanced loading will be 19 tons per square foot.

Waterproofing and Drainage—Experience with several structures of this type built about 15 years ago has shown that to avoid deterioration thorough waterproofing and ample drainage are necessary, and considerable study has been given to this detail. The deck will be sharply pitched to drains between the spandrel arches and waterproofed with a membrane, which will be protected with concrete. The fill between the ballast and deck will be of coarse material to permit free passage of water to the drain heads. The expansion joints over the piers and abutments will be flashed and counterflashed with copper, and the tops of the drains fitted with cast-

FIG. 2—CONSTRUCTION WORK AT BRIDGE SHOWING ARRANGEMENT OF PLANT AND ARCH CENTERING

iron flanges to flash and counterflash the membrane at this point. The deck drains lead through the pier walls, discharging into a channel on top of the main arches which will carry the water through the piers to the outlet. The lower portion of the chamber in the pier will be waterproofed to prevent seepage in case the outlet drain is clogged.

The structure will contain about 27,900 cu.yd. of concrete and 900,000 lb. of reinforcement.

Construction Plant—The arrangement of the contractor's plant for handling the material is interesting, and is shown in some detail in the accompanying sketch. The concrete materials are received on a track from the B. & O. R.R. about 1,000 ft. west of the bridge and on high ground, are unloaded by a locomotive crane and stored in piles over a timber tunnel through which tram cars run. The concrete aggregate is delivered through hoppers to the cars in measured quantities, and the bags of cement are placed on top. The cars run down an incline to the bridge, where the cement is added, and each car, containing one batch, is dumped into a hopper from which the mixer is charged. At first the cement was emptied on top of the aggregate in the car before leaving the tunnel, but it was found that there was some loss during the trip down the incline, especially in windy weather. The cars are operated in two trains, of 4 cars each, on a cable, and from the storage piles to the charging of the mixer practically all of the work is done by gravity. All laborers except those at the forms are under shelter, and continuous mixing and placing of the concrete is limited only by the formwork.

The mixed concrete discharges directly into the hoist of a 150-ft. steel tower and is distributed by chutes to most of the forms. In the abutments it was necessary to rehandle it by bucket and derrick, and for placing the concrete in the end spans and superstructure the chutes discharge into a car operating along an

elevated trestle, which empties into distributing chutes. The inclination of the tower chutes was kept within the limits of 1 to 3 and 1 to 2. Each batch of concrete was mixed at least 50 sec. and for longer periods when it had to be rehandled by cars or buckets.

The excavation for the foundation was made by a 7-ton locomotive derrick on the west side and a 20-ton traveling stiff-leg derrick on the east side. These derricks were also used for rehandling the concrete from the chute to the forms which could not be reached by the tower, setting arch centers, etc.

Steel Centering, Camber and Deflections—Steel centering was used for all spans. Each set of centers consists of four ribs, which are three-hinged arches with bottom ties. They are made wide enough to pour one half of each arch. 16½ ft., and are rolled sideways, with the lagging intact, for the second half of the ring. Each half of each ring is poured in *voussoirs* of such size and in such order as to cause no undue reversal of stress in the arch centers. The centering is supported on double timber bents resting on top of the footing courses.

The trusses were cambered about one inch, and to allow for the take-up in the bents and blocking the shoes were set about 1 in. high. After the rings were poured elevations were taken on the 140-ft. spans and it was found that at the crown there was a settlement of about 2 in. and at the shoes about 1 in., verifying the original assumptions. After the centers were lowered (on the spans poured to date) elevations were taken on the arch ring to determine what settlement had occurred under dead-load, but none was apparent. The computed deflection at the crown of the 140-ft. span was found to be only 0.001 ft., and this was probably neutralized by the lengthening of the arch ring under rise in temperature. In fact there is some evidence that the rings had actually lifted themselves from the centers, as the wedges under the shoes were easily

backed out, although the computed load on the centering was about 1,700 tons. This condition would probably be reversed for arches poured in fall and winter.

Permanent points are being placed at intervals on one 100-ft. and one 140-ft. span, and it is the intention to take frequent elevations to determine the deflection as the work progresses and as the superstructure is added, and for some time after the completion of the bridge, under various ranges of temperature.

The centers were not lowered until 25 days after pouring of the arch ring, and 15 days after the last pouring on the adjacent spans. Due to the deflection of the centers under load, it was necessary to use some care in adjusting the centers for the second half of the ring in order to avoid a lip at the joint. After the centers were moved over, the inner truss was so near the completed ring that the crown was restrained and it was possible to jack up its bearings and introduce some initial deflection. This left the outer truss about one inch high at the crown, to deflect under load. To conceal a possible lip, a 4x6-in. channel was formed in the intrados where the two halves joined.

After the concrete is poured an effort is made to keep it damp for at least two weeks. The tops of the arch rings are sprinkled several times daily, and as the deck is completed, the drain holes are plugged and it is flooded.

Proportioning the Concrete—Practically all concrete work of the company in past years had been poured under the ordinary specification, using the standard 1:3:6 or 1:2:4 mix, with probably average supervision but without especial care being given to the grading of the aggregate or the consistency of the mix, and some of this concrete has not been entirely satisfactory. It was felt that the importance of this particular structure required some unusual effort to assure the proper mixing and placing of the concrete, and, owing to the large volume, it offered an excellent opportunity to experiment with the method proposed by Prof. Duff A. Abrams, of the Structural Materials Research Laboratories, Lewis Institute, for the design of concrete mixtures. This method had been developed and confirmed in laboratory experiments but had not been used in the field to any great extent and there was some doubt as to the possibility of approaching the laboratory results, but it seemed that at least the mere moral effect of making the tests promised better concrete, and it would determine the practicability of adopting this method on future work, where there was sufficient yardage to justify it, and that possibly some evidence as to correctness or inconsistencies of present specifications and methods could be obtained.

It was decided to use mixes to produce concrete of the following strengths:

	Lb. per sq.in.
Footings	2000
Piers and abutments	2500
Arch rings	3000
Spandrel arches	2500

In the footings, piers and abutments, a premixed aggregate (concrete gravel) was used, of size 0 to 1½ in. The fineness modulus varied from 5.3 to 6.7, with an average of about 5.9. This wide range was probably due to separation of the sand and pebbles in unloading, and as the stockpile was large and the hoppers drew from the center of it the fineness modulus was

uncertain, differing from day to day, and it was almost impossible to adjust the mix for the frequent variation in the aggregate. After some experimenting, it was found that, to avoid clogging the chutes, an average consistency as represented by a slump of 6 to 7 in. was required. The batches were 23.3 cu.ft. and the yield, or the ratio of the volume of finished concrete to the volume of loose damp aggregate, was assumed as 90 per cent to find the nominal mix, the true mix necessary to produce the required strengths being known after the consistency of the mix and characteristics of the aggregate had been determined. Including waste there were poured about 10,440 cu.yd. of gravel concrete, requiring about 11,700 cu.yd. of aggregate, which gives a yield of 89.0 per cent.

For the arch rings and spandrel walls separate aggregates are being used, the sand ranging from 0 to ½ in. and crushed boulders and pebbles from ½ in. to 1½ in. The fineness modulus of the fine and coarse aggregates remains quite uniform, averaging 3.2 and 7.8 respectively. For the arch rings the batches consist of 11 cu.ft. of sand and 17 cu.ft. of stone, and the mixture has a fineness modulus of 5.95. For the superstructure there is used 12 cu.ft. of sand and 16 cu.ft. of stone in each batch, the mixture having a fineness modulus of 5.8. The sand and stone when mixed should produce about 23.8 cu.ft. of gravel or 85 per cent by volume. The 23.8 cu.ft. of gravel should produce about 21.4 cu.ft. of concrete (90 per cent) or, the ultimate yield would be $28 \times 0.85 \times 0.90 = 21.4$ or about 76.5 per cent. To pour 4,800 cu.yd. of concrete required about 6,400 cu.yd. of separate aggregates, which gives a yield of 75 per cent. Tests were made on several batches and it was found that 28 cu.ft. of sand and stone would produce about 22.5 cu.ft. of concrete (80 per cent) in the bucket at the mixer, but there would probably be further shrinkage by the time it is placed in the forms.

The accurate determination of the yield is important, as by this factor alone can the nominal or working mix be found after the true mix, for the required strength, is known. It has been determined in the laboratories, but with comparatively small volumes and under somewhat different conditions than those which exist in actual construction. The amount of moisture initially contained in the aggregate materially affects the yield and this must be allowed for.

It was found that the concrete made of separate aggregates could be easily handled in the chutes and forms with a slump of 3 to 4 in. In fact many batches were poured in which the slump was 1½ to 2 in., the average being about 3½ in. This produces a concrete much drier than it was thought could be handled through the chutes, and much drier than the gravel concrete previously poured with the same equipment. This seemed difficult to explain as the gravel, sand and pebbles were from the same pit, but it is undoubtedly due to the fact that the fineness modulus of the sand and pebbles remained nearly constant and that the mixture was such as to produce a very "workable" concrete, while the gravel varied greatly and was often of such a nature that it required an excess amount of water to make it workable. This same fact was observed in another structure containing about 6,500 cu.yd. of concrete, built under a different inspector. Here the concrete was largely placed by buckets, but to get a good face on finished work required that the gravel

mix have a slump of about 7 in., while the concrete made of separate aggregates worked nicely with a 3-in. slump. In one structure where a premixed aggregate was used throughout, the gravel being handled in small quantities and in such a manner that little or no segregation occurred, the fineness modulus remained nearly constant, it was found that concrete could be mixed with good results to a consistency represented by a slump of 4 in.

Unless it is certain that the grading of the premixed aggregates is proper and will remain fixed, there seems little justification for its use. The ease of handling from a single stockpile is of some advantage, but this is far outweighed by the cost of the additional cement required in the wetter concrete of equal strength, and by the increased workability of the mixture made from the separate aggregates used in the proper proportion.

There has been an almost general condemnation, in which the writer joined, of the tower and chute as a means of distributing concrete, as this method seems to require very wet mixtures and often results in com-

plete separation of the mortar and stone. On this work, however, there has been several thousand yards successfully placed by chutes, much of the concrete being drier than any heretofore handled by other methods and delivered with no separation. Possibly the use of excess water is largely habit and probably the segregation is due to the use of improper materials poorly proportioned and insufficiently mixed.

The Abrams method of designing concrete mixtures was employed on several of the larger structures representing about 50,000 cu.yd. of concrete, and as a check test specimens are made at frequent intervals.

These test pieces are 6x12-in. cylinders, made in accordance with the A. S. T. M. Standard (Serial C-31-21) except that instead of taking the sample from the form it is drawn directly from the discharge of the mixer, so that the actual slump of the sampled batch could be measured. From three to six specimens were made for a day's run, from different batches, stored in wet sand and tested at the end of 28 days. About three hundred specimens, representing various mixes, and

slumps ranging from 1 in. to 8 in., have been broken to date, and several hundred tests will be made before the completion of the work.

The first results were disappointing; many of them showed strengths lower than expected and the others were quite erratic. While it was considered that average care had been exercised in making the specimens, investigation showed that there had been some minor departures from the recommended methods, especially in capping and storing the pieces, and after this was corrected the results were quite consistent, agreeing closely with the tables published by Prof. Abrams.

The concrete work will not be completed for several months, when additional information will be available from which more definite conclusions can be drawn, but it seems apparent:

1. That the method of designing concrete mixtures, as worked out in the laboratory, is applicable under field conditions and that a concrete of predetermined strength can be obtained with considerable accuracy, by using the proper mix and consistency.

2. That quite dry concrete, of aggregates properly proportioned, can be worked without difficulty and handled by the usual methods, and with considerable saving in cement over that necessary in the wetter mixtures of equal strength.

3. That a specification, simply defining the mix as 1:2:4 and 1:3:6, etc., without establishing some further requirement as to the consistency and grading of the aggregate, means little from the standpoint of strength as the results may vary 100 per cent, and consequently such a specification is uneconomical.

4. That better results can usually be obtained with concrete made from separate aggregates (sand and stone) than from a premixed aggregate (gravel).

5. That unless inspectors who are familiar with this method of proportioning concrete are available, it is scarcely practicable on small work as it takes them some little time to learn the mechanics of the tests, and longer to completely grasp the theory, so as to be able intelligently to vary the mix under the different conditions of weather, material, and pouring. Where frequent sieve analyses and slump tests are made it requires a good deal of the inspector's time, and on large and important work a special man to make the necessary tests would probably be justified.

The Walsh Construction Co. of Davenport, Iowa, has the general contract for the grading and masonry, and is constructing the Miami River Bridge. The work is being done under the general direction of C. A. Paquette, chief engineer, C. C. C. & St. L. Ry. Co.

Reports on Decay in Douglas Fir

Because Douglas fir is one of the most important timbers of the United States and because it is very susceptible to diseases caused by four fungi which attack it, the United States Department of Agriculture has made preliminary investigations to determine the extent of such damage and the amount of defective timber. The results of the investigations so far made have been published in the department's bulletin No. 1163, which may be had upon request from the Department of Agriculture in Washington. The facts so far established are that young stands or second growths are relatively immune from decay, but it is not yet known at what age this immunity ceases.

Sewage Distribution Tests With Butterfly-Valve Control

Variation of Pressure at Taylor Sprinkler Nozzles Obtained by Cam Control of Valve—Time-Pressure Curve

BY HENRY R. KING

Junior Assistant Engineer, Sanitary Division,
Sanitary District of Chicago

IN THE course of recent experiments on sewage distribution by means of sprinkler nozzles the author was impressed by the value of a butterfly valve for close control of variations in loss of head. By using the butterfly valve data can be obtained which may be more easily applied in the design of dosing tanks and other arrangements for trickling-filter control than the data which are now available. The experiments were made by the writer last year as a part of work for a thesis at the University of Illinois.

Previous experiments in sewage distribution have generally been tests of the distribution occurring with different types of nozzles when discharging at different fixed pressures. Examples of these are the recent tests

FIG. 1—METHOD OF CONTROLLING BUTTERFLY VALVE TO GIVE VARIABLE SPRINKLER-NOZZLE PRESSURE

of sprinkler nozzles by the Pacific Flush Tank Co. of Chicago and by the Purdue University testing station. The results obtained at these places have considerable value and afford examples of the best data available for designing controls for trickling filters.

Since in the operation of trickling filters a variation of pressure must occur at the nozzles to secure a uniform distribution, some difficulty arises when it is attempted to apply data given for nozzle operation at fixed pressure to conditions of varying pressure. The desired information may be arrived at by a tedious mathematical computation which has proven sufficiently difficult to result in a difference of opinion among engineers as to the proper shapes for dosing tanks.

In the sewage distribution experiments performed by the writer, a battery of three $\frac{1}{2}$ -in. Taylor circular-spray nozzles, spaced 14 ft. apart on the apices of an equilateral triangle, was used. Instead of operating these nozzles under various fixed pressures, as has been the usual practice in such experiments, a variation of pressure at the nozzles was effected. To secure this, a butterfly valve (see Fig. 1), operated by a cam revolving at a constant rate, was placed in the supply pipe to the distribution system. Sewage was supplied from a tank in which a constant level was maintained. The butterfly valve served to produce a head loss between the tank and the nozzles, the extent and variation of

FIG. 2—RELATIVE SEWAGE DISTRIBUTION BY NOZZLES

which depended on the shape of the cam operating the valve.

To study the distribution effected, the triangular area between the nozzles was marked off into 1-ft. and smaller areas of different forms (Fig. 2). Pans, with their tops at the same elevation as the nozzles, were placed on these subdivisions. The spray that collected in these pans was measured after each dosing cycle. Distribution was considered good when between 87½ and 112½ per cent of the mean rate. For the underdosed area receiving 75 to 87½ per cent of the mean rate, the distribution was considered fair. The distribution on the remaining area was considered poor whether underdosed or overdosed.

The cam was symmetrically shaped (Fig. 1) so that the pressure at the nozzles rose from zero to a maximum and returned to zero, thus giving a symmetrical pressure-time curve. In the experimental procedure a cam was designed theoretically and tested. It was then altered until a satisfactory distribution was obtained on the triangular area between the nozzles. Fig. 2 is a graphical representation of the final distribution effected.

In Fig. 3 the head on the ½-in. Taylor circular-spray nozzles, spaced 14 ft. apart, is plotted in relation to time for the distribution shown in Fig. 2. The curve shows the relation of the head to the decimal parts of the total time for a variation of head from zero. The data

FIG. 3—PRESSURE-TIME RELATION DURING DISCHARGE PERIOD OF SEWAGE-SPRINKLER NOZZLES

Taylor ½-in. circular spray nozzles were spaced 14 ft. apart, as shown in Fig. 2. Each nozzle discharged 18.15 gal. in a one-minute discharge period and had 170 sq.ft. effective sprinkling area.

for this curve were obtained by noting the positions of the cam and the simultaneous pressures at the nozzles, as observed from a pressure gage connected to the distribution system adjacent to one of the nozzles. The angular position of the cam divided by the total angle of discharge gave the decimals plotted as abscissas in the diagram.

It is evident that curves similar to that of Fig. 3 for all sizes and spacings of sprinkler nozzles would be particularly valuable for designing dosing controls for trickling filters. Information presented in such form would have decided advantages over the data that are now furnished the engineer. It is the pressure-time curve in which the engineer is interested and which he must obtain to design a dosing tank properly. If such curves were provided him, together with the distribution results that had been experimentally obtained in their preparation, the design of trickling-filter controls would be considerably simplified.

The ease with which the pressure-time curves could be used for determining the proper shapes for dosing tanks is apparent from Fig. 3. The actual curve approximates a parabola. Therefore the time from zero head to any head upon the nozzles should vary approximately as some constant times h^2 for nozzles and spacing the same as used in the test. Let A equal the horizontal sectional area of the dosing tank at any distance above its bottom and T equal the time from zero head to any head upon the nozzles or from the pressure-time curve $T = k'h^2$. The rate of discharge $= k'' \sqrt{h}$; $dV = Adh$; $dT = Adh \div k'' \sqrt{h}$.

Taking the derivative of T as given by the pressure-time curve, $dT = k'''hdh$, and equating, $k'''hdh = Adh \div k'' \sqrt{h}$ and $A = k h^{3/2}$. Therefore for a 14-ft. spacing of ½-in. Taylor circular-spray nozzles (disregarding frictional losses) the horizontal sectional area of the dosing tank should vary as some constant times its height above the nozzles raised to the 3/2 power.

Other factors would necessarily have to be considered in such a design but the general shape of the dosing tank could be obtained from the relation given.

Sewage Gate-Valve Forced Off Pump Main

A 12-in. gate-valve on the pump-well end of a branch pipe 20 ft. in length, connected with the 14-in. force main at the sewage pumping station of Natick, Mass., was recently forced off by the pumping pressure so that the contents of the entire length of the force main (6,000 ft.) and also of one sewage-bed were emptied into the pump well. The gate was on the extreme end of the branch pipe and was held in place by an ordinary lead joint, but there was a head at the spigot end entering the gate-valve. There was no pipe beyond the gate leading into the well. The pressure ordinarily carried by the gate, which had been withstood for twenty-seven years, was about 40 lb. The gate was customarily kept closed and was opened only when it was desired to repair the force main. *Engineering News-Record* is informed by Frederic I. Winslow, Framingham, Mass., who sent the information given above, that it is probable that the action of gases from the sewage caused the lead in the joint to deteriorate to such an extent that the joint gave way. To lower the level of the sewage in the pump well, fire engines were used and the sewage was pumped to the ground so that the gate could be replaced.

Large Eyebars Suspension Bridge in South America

Span of 1,114 Feet Under Construction in Brazil
Has Chain of Eyebars with New Form
of Stiffening Truss

A COMBINED highway and railway bridge under construction at Florianopolis, in the province of Santa Catharina, Brazil, connecting the island on which the city is located with the mainland, represents the first application of modern eyebar-chain construction to suspension bridges. It is no less interesting because of its unusual stiffening truss construction, which, in connection with the use of eyebars for the chain and the unloaded backstays, results in a high degree of rigidity and economy. Because of its long main span, nearly 1,114 ft., this structure will take rank among the largest suspension bridges in existence. It was designed by Robinson and Steinman, of New York, as consulting engineers for Byington and Sundstrom, of São Paulo, Brazil, contractors for the bridge.

In the original design for the crossing, whose span is controlled very closely by the conditions of the site (see the location plan), a wire-cable suspension bridge was contemplated. This design had a parallel-chord stiffening truss with hangers at all panel points. When, however, the American Bridge Co. made a tender of heat-treated eyebars under a guarantee of 75,000 lb. per square inch minimum elastic limit, permitting a working stress of 50,000 lb. per square inch to be used in the chain, the structure was redesigned to take advantage of eyebar construction, with the result of showing a distinct economy in total cost and permitting the stiffness of the main span to be increased very greatly. The eyebar-chain design, shown in the drawings, is now being carried out.

Special Features—From the design details on p. 593 it will be seen that the towers are two-column steel bents with battered legs and with line bearing at the base, while the stiffening trusses have curved top chords so disposed as to give maximum depth at the quarter-points, the top chord in the middle section being formed by the suspension chain itself. This novel combination of chain and truss yields large savings in steel due to the elimination of the middle half of the top-chord and other members, and to the more economical truss outline in which the depth conforms to the variation in bending moments along the span. The traffic requirements are satisfied by a 28-ft. clear roadway width, which fixed the truss spacing at 33½ ft. Accordingly the cross-section involves no features beyond the ordinary. The backstays are unloaded, going down directly to masonry anchorages, one of which is on rock while the other is carried by a pile foundation including both vertical and batter piles. The approaches are steel viaducts with spans of 185 ft. directly adjacent to the towers.

Loading—The loadings assumed for the design of the various parts of the structure vary from 1,850 lb. per lineal foot of bridge for the chain and 2,000 lb. for the trusses (the latter with 10 per cent impact) to a 6-ton truck or 60 lb. per square foot (with 25 per cent impact) on the roadway stringers, and a 50-ton electric locomotive followed by 2,000 lb. per lineal foot (50 per

cent impact) on the railway stringers. Wind was taken at 25 lb. per square foot on the suspension bridge and 30 lb. on the viaduct, and the temperature variation was taken at the moderate amount of 30 degrees rise or fall, in conformity with local climatic conditions. In comparison with these figures it may be noted that the total dead load is 4,370 lb. per lineal foot of main span, or about 4,000 lb. for structure and deck excluding the water main which extends along one side of the roadway.

With this loading the greatest allowable stresses were set at 50,000 lb. per square inch for the eyebars of the main chain, and 20,000 lb. per square inch in the stiffening trusses. Some margin below these amounts was maintained, however, and the final stresses in the chain do not exceed 46,500 lb. per square inch, and those in the trusses 18,500 lb. per square inch, as calculated by the ordinary, approximate method. In the case of the stiffening trusses, additional margin is represented by the difference between analyses of the structure by the ordinary method and by the more exact or deflection method; the latter showed considerably lower stresses, by about 25 to 30 per cent, but no reduction in section was made to suit these stresses. The reduction in the chain stress was made possible by the smaller weight of the combination stiffening truss of variable depth as compared with the parallel-chord truss. The floor framing has its bending stresses limited to 17,000. In all the analyses, the value of the modulus of elasticity of the truss steel was taken at 29,000,000 lb. per square inch and that of the eyebars was taken at 27,000,000 lb.

The two chains consist each of four eyebars 12 in. wide, from anchorage to anchorage. The eyebars of the backstays are 2 in. thick, while those of the main span range from 2 in. to 1½ in., with chain section ranging from 96 to 87 square inches. Steel-rope suspenders are used, consisting of two parts of 1½ in. galvanized steel wire rope socketed to clevis attachments at the top chords of the trusses.

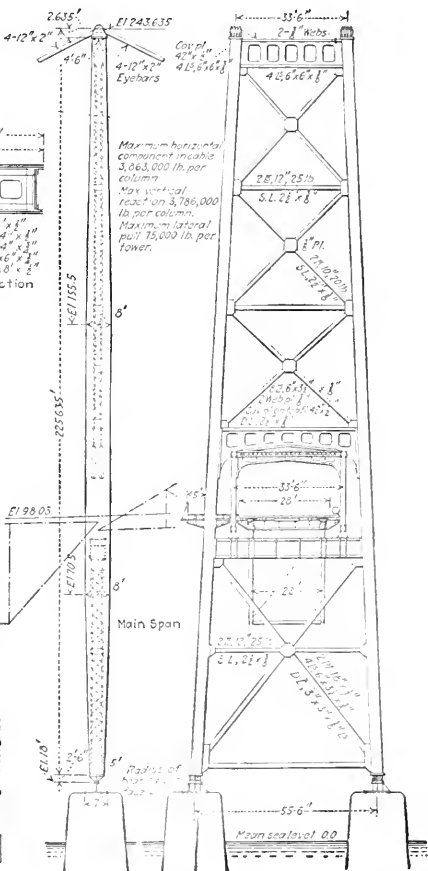

Calculations of the deflections of the structure show that under live-load on one-half the span, the quarter-point deflection is only about 13 in., or 1/1,000th of the span, while under full-span loading the center deflection is about 17 in. or about 1/800th of the span. These extraordinarily low values result from the following factors: the use of eyebars in the chains, with their greater section and resulting greater dead weight and reduced elongation; the unloaded backstays; the great depth of stiffening truss at the quarter-points, about double the depth of the originally-planned parallel-chord truss; the large chord-section of the stiffening trusses in the middle portion, where the chains serve as chords; and the novel combination of chain and truss whereby full live-load produces tension instead of compression in the middle half of the top-chord.

Construction and fabrication are now under way and the bridge is expected to be completed by the end of next year.

MAIN FEATURES OF EYEBAR- CHAIN SUSPENSION BRIDGE, FLORIANOPOLIS, BRAZIL.

This eyebar-suspension bridge has a span of 1,113 ft. 9 in., which makes it one of the longest suspension bridges ever built. Note the unusual stiffening trusses with use of suspension chain in combination.

Highway Construction in Panama

Traffic Growing Rapidly on Completed Roads—Bridge Building Experience—
Local Labor Notably Steady and Efficient for Tropics

BY R. C. HARDMAN

Acting Chief Engineer, Junta Central de Caminos, Panama

HIGHWAY development in Panama is drawing to the close of its first phase and is about to enter upon its second phase. The groups of roads tributary to important ocean ports, begun in 1920, will be virtually completed this year. This constitutes the first development phase. The second phase, now planned and being financed, is the extension of these isolated roads to connect with each other and with the city of Panama. Both the original and the planned routes are indicated on the map, Fig. 1.

Isolated Group Development—Feeling the necessity of transforming the nation from an importing to a possible exporting one, the National Assembly, activated by the progressive policy of the president, Dr. Belisario Porras, passed on March 13, 1919, the first of a number

ence in the Philippines, was named for, and appointed to the position in August, 1920. Upon his resignation in October, 1921, he was succeeded as chief engineer by R. K. West, of wide highway experience in the Philippines, California and Nevada.

In the budget for the biennium ending June 30, 1921, 75 per cent of the excess of receipts over the amount estimated in the budget was set aside as a road fund. Under the able management of Addison T. Ruan, fiscal agent for the republic, this fund at the close of the biennium amounted to \$3,092,225.92.

Topographical Conditions—A word might be said concerning the topography of Panama. The narrow isthmus forming the republic has a high mountainous backbone rising to a culmination in the Volcan de Chiriqui, near the Costa Rican border, at an elevation of some 11,280 ft., and reaching a minimum of a few hundred feet at the Panama Canal.

The Atlantic side is, in general, of narrow steep slopes merging into mangrove swamps, while the Pacific slope is much wider, of more gentle declivities, of rolling, grassy plains or llanos, and has a multitude of rivers. Practically all the settlement of the country is on the Pacific side and to the west of the canal. Due to the high tides of the Pacific and the shoal waters near the coast, no natural harbors are to be had. Several small ports, for shallow draft vessels at high tide, furnish the only connection between Panama and the agricultural provinces. Transportation in all the interior districts has been for centuries, and still is, almost entirely by ox-cart and pack-horse for cargoes, and saddle-horse for passengers, over roads and trails which in the dry season are mere ruts and in the rainy season seas of mud, practically impassable. As the rainy season lasts for seven or eight months, the need for passable highways is apparent.

The Central Highway Board, after careful study of the matter, adopted for improvement two sets of roads: one based upon the ports of Chitré and Mensabé, the other based upon the ports of Aguadulce and Obaldía as important points.

The first systems of roads provided for were designed to develop the ports mentioned above, in the vicinities of which several producing sugar mills are in operation, and from which a large part of the beef consumed in Panama is shipped. In the light of the Gulf of Panama, upon which Aguadulce is located, the convergence of the drainages from the continental divide and the mountains of the peninsula to the south forms a low,

FIG. 1—HIGHWAYS UNDER CONSTRUCTION AND PROJECTED IN PANAMA

of laws concerning highways and the development of Panama's hinterland. This initiatory law provided for an annual contribution, or road tax, from all able-bodied males between the ages of 21 and 70, who were placed in three categories, of \$12, \$5, and \$3, depending upon the financial standing or earning capacity of the contributor. It also provided for district highway boards to carry on minor works out of the funds so created.

This law was followed on Feb. 6, 1920, by one creating a central highway board, consisting of the secretary of the interior and public works, as president; the fiscal agent of the republic, the chief engineer, as executive officer; and two citizens; and this board is to have in its charge the location, construction and maintenance of all roads in the republic and supervision over the local boards created by the first act. As the law contemplated the employment of a foreigner as chief engineer, the U. S. State Department was requested to make a selection and through the Panamanian Legation in Washington J. W. Beardsley, of long highway experi-

FIG. 2—STANDARD SECTIONS FOR PANAMA HIGHWAYS

flat alluvial area which is very fertile, and which is tapped by the system of roads centering on this port.

Considering the population, economics and probable future traffic, the Central Highway Board very wisely adopted the macadam type of road 3.5-m. surfaced width, with drainage structures of steel and concrete, as the most suitable under the existing and probable future conditions. Provision was also made in grade and structures, for future widening of the road when increased traffic might warrant.

History.—Proposals for the two systems of roads decided upon were advertised for in January, 1921. As the board had no technical organization and it was desired to start the work without delay, bids were requested for construction and also for surveys and plans, on the basis of cost-plus-a-percentage, with bonus and penalty clauses. Awards were made to R. W. Hebard & Co., New York, for the Aguadulce system and to the Panama Construction Co., Panama, for the Chitré group, and the work of surveying started in April, 1921, on both divisions.

Each division, sub-divided into four sections, comprised in all, about 135 km. of road. Due to various causes, among which was the business depression and transference of funds to other branches of the government, of the 270 km. in the two divisions, only about half of the proposed program has been authorized and is actually under construction.

In addition to the work in the interior provinces, there was planned a highway from the city of Panama to Juan Díaz, with a short branch to the ruins of Old Panama, which was destroyed by Sir Henry Morgan in 1671. Of this section, 3.37 km. are of concrete, 6 m. in width; 5.30 km. of bituminous concrete, 5 m. in width, and 10.60 km. of oiled macadam, 3.5 m. wide. This is the only highway out of Panama on Panamanian territory and affords an outlet for the rich agricultural districts to the east which have been lying dormant because of a lack of transportation facilities. As an indication of what may be expected in the way of development, a comparison of present traffic on this road with conditions of two years ago is enlightening. The writer, early in 1921, went to Juan Díaz in an automobile, engaged after considerable effort, for \$7.50. In the last week of March, 1923, a traffic count at Juan Díaz showed a daily average of 231 motor vehicles, with a maximum of 372 and a minimum of 163. The fare in any one of a number of motor buses is now 50c. for the round trip. On the first or concrete section of this road, the daily motor-vehicle average count was 1275.1, with a total motor-vehicle registration of but 1,220. The maximum for this section was 2,942 and the minimum was 853.

Types of Roads.—On the interior roads, which are not yet fully completed, equally remarkable traffic increases are expected. Where two years ago motor-vehicles (other than airplanes) were unknown, large numbers of passenger cars and light trucks are in operation, and

bus services between towns, which are already connected, have been established.

The roads at present being completed in the interior are, as before stated, of the light-surface type, macadam or gravel with permanent structures of concrete and steel. The width of surfacing adopted was 3.5 m, on a grade width of 6 m., shoulder to shoulder. Structures, however, were designed for a 5 m. clear width, with the exception of long steel spans which are 4 m. This clearance on steel spans was fixed partially by that of some long steel spans already existing on the adopted routes and by the large number and consequent great cost of steel bridges required on the proposed work.

The typical cross-section of the road is as shown in

FIG. 3—TYPICAL STREAM SECTIONS AND BRIDGES

Fig. 2. The width of surfacing, as well as its thickness, was the subject of much discussion and study, and those adopted, after a year's observation since the completion of certain portions of road, have been proven to be ample for the amount and weight of traffic.

Construction in the main has been largely by hand labor, especially on earthwork. Mechanical equipment for earth moving has not shown the most favorable results due to the lack of capable operators. A certain amount of patience is necessary to secure the interest of the local operative candidates. One crew has been developed for use on a blade grader drawn by a 40-hp. tractor which has performed very satisfactory service, and with additional practice and training excellent results may be expected. One favorable feature is that the native becomes a steady worker after learning the use and object of mechanical appliances.

Considerable difficulty was anticipated in securing common labor in the provinces, but happily without justification. A steady reservoir of labor has been available, which, although untrained in any but agricultural work, has proven itself fairly adaptable and efficient. Studies made for the year 1922 show that the attendance efficiency of hourly men, measured in terms of hours worked to possible hours of work, has a steady increase throughout the year. Aiding in this was the medical and sanitary supervision exercised by the contractors and an uncinariasis campaign carried on by the Rockefeller Foundation over a part of the period. The common labor is also very quiet and manageable, which in itself tends to increase efficiency in attendance.

Efficiency in output has been good for tropical labor;

FIG. 4—ASPHALT ROAD NEAR PANAMA

especially is this true on task work. On excavation in ordinary earth, tasks of four to five cubic meters are given, depending upon conditions. The average task laborer moves 5 c.u.m. in from seven to eight hours. Quarries operated by task labor show an output of about 7 c.u.m. per man per nine-hour shift.

An interesting experiment was made with a small gang on earth borrow to determine the merits of the task system. The results were startling. Twenty-one men under a native sub-foreman moved 8 c.u.m. in 9 hours. Five of the same men the next day moved 23 c.u.m. in the same period by task.

Proposed New Development—As the roads now completed and under construction in the interior are merely for the development of the country adjacent to the ports, their full purpose will not be realized until the systems are connected to each other and to the capital, Panama. Panama, in common with all other undeveloped nations, is distinctly provincial in nature, due entirely to lack of means of transportation between the integral parts. Consequently proper united action for the benefit of the country as a whole is difficult, and only by furnishing connections can unified action be expected. Realizing this, the president, Dr. Belisario Porras, has secured the necessary legislation for the

floating of a loan to cover the cost of bringing the present roads to the capital.

The map, Fig. 1, shows the roads already constructed and to be finished by the end of the fiscal year, and those proposed to be built with the proceeds of the authorized loan of \$4,500,000, negotiations for which are now under way.

From the point where the present construction stops, at Natá (founded in 1519) to the Canal Zone boundary is approximately 160 km., over a terrain extremely varied, running from low, alluvial river bottoms, through high, grassy plains, broken and eroded waste lands, to high, fertile jungle-covered hills at its terminus at the Canal Zone boundary. Unfortunately, during the construction of the Panama Canal, no provision was made for a permanent crossing, so that now no means exist for transportation from one part of the republic to the other except by water, or by horse across the lower guard gates on the locks. Consequently, a system of highways such as is contemplated, will be defeated in its purpose without the co-operation of the United States government in providing a permanent crossing of the canal and the constructing of a highway from the canal to the boundary. That such co-operation will be given is not to be doubted, as the military value of the work will equal, if not transcend, its economic importance, not only by enabling the rapid movement of the troops over a now practically impassable region, but by the much greater factor of opening up territory to the cultivation of foodstuffs sufficient to sustain the military and civilian population in case of possible blockade by an enemy fleet. Under present conditions, due principally to a former policy of isolation and the depopulation of the Canal Zone, contiguous to the only available transportation—the Panama Railroad—practically all foodstuffs are imported from abroad, or are brought to Panama by water.

The proposed road connecting Natá with the capital presents some difficult terrain, the Natá end for several kilometers being through river bottoms subject to overflow and necessitating practically a continuous fill for about 15 or 16 kilometers. It then merges into a high, grassy plain gradually changing into waste lands characterized by deep, badly eroded gullies and deep, narrow stream channels. In 9.6 km. of this section there will

FIG. 5—TYPICAL LABORERS' CAMP

be eight stream crossings with some 640 m. of steel bridges—nearly 7 per cent of the distance. Leaving this broken country, the line crosses high, jungle-covered hills near Capira, merging again onto grassy plains in the vicinity of Chorrera from which point the wooded hills continue to the Canal Zone boundary.

Owing to the extremely broken topography along streams, in some cases 10 per cent grades are necessary for short distances, while on the Capira hill section 7 and 8 per cent grades are required to reach the summit of the entire line which is at 203 m. above sea level. In general, no grade will exceed 7 per cent. The maximum curve planned is 40 deg., metric-radius about 29 m., although this may be exceeded in some unavoidable instances.

Owing to the nature of isthian topography, which

FIG. 6—"CASCAJO" ROAD NEAR AGUADULCE

"Cascajo" means "gravel," but the soil near Aguadulce which is composed of clay, feldspar, decomposed feldspar, hematite and limonite is also so called.

in the hill sections is made up of numberless small round-top hills with no semblance to order or regularity, the alignment is not simple, although in the plains sections tangents several kilometers in length are easily obtainable.

On the entire route from Natá to the Canal Zone, the projected line shows a total of over 2 km. of steel structures in a distance of about 165 km., having an estimated weight of some 1,600 tons. This work presents the greatest construction difficulty, as transportation in a territory devoid of roads is a serious problem. Not only must steel and cement be hauled from the ports, but in many cases stone, gravel and sand must also be transported long distances. Sand in some sections is unobtainable, in others practically a pure quartz sand is found in large quantities.

Cross-sections of five of the 38 major streams to be crossed in the 165 km. are shown in Fig. 3. These show the three types of stream, the deep, narrow gorge of the waste lands district, the unbalanced bank type of the hill sections, and the low overflow stream of the plains area. Cantilever spans are proposed for some of the wide, deep gorges, as timber for falsework is not available locally and imported sawed timber is almost prohibitive in cost.

Streams of the type of the Capira and Perequeté are usually at the foot of long heavy grades, on the high bank side, that at the Capira being approached by 1,340 m. of an average grade of 4.85 per cent.

The surfacing problem is a difficult one as good rock

is very scarce and gravel is even more so in certain sections. Several kilometers of roads now under construction have been surfaced with a soil known locally as "cascajo," which is found over an area of several square kilometers and is composed of clay, decomposed feldspar, hematite and limonite. The material when taken out is yellow, but after a few days on the road becomes an iron oxide color, very hard and practically impervious. In other sections is found a sand-clay mixture which with some addition of sand will form the hard or Class A material of the State Highway Testing Engineers and Chemists conference. In the hill sections, suitable stone is available with reasonable hauls.

Of the other proposed roads, those out of the city of Colon will be the most beneficial, opening up as they will some very productive lands. The short road from the end of the railroad in the western end of the country will tap some very fertile lands on the slope of the Volcan de Chiriquí, which have recently been acquired by a large group of colonists from southern California. The route to Chepo to the east of Panama is but an extension of the road for which some traffic statistics have been given above, and with the western extension to Santiago will provide a con-

FIG. 7—TYPICAL REINFORCED-CONCRETE GIRDER SPAN ON NEW WORK

Old bridge visible in background.

tinuous road from east to west of some 220 km. through a region which is expected in the near future to place Panama on the list of exporting nations.

Since the beginning of the highway work two years ago, great enthusiasm has developed along highway lines; enthusiasm which has in many instances resulted in work being done on short connections by voluntary contributions of labor and transportation.

The personnel of the organization handling the highway work is J. M. Fernández, secretary of interior, as President; R. K. West as chief engineer; F. H. Baldwin, sub-fiscal agent for the republic; Rafael Neira A., and Gregorio Miró, members, and Alfredo O. Boyd, secretary. Credit for assistance on financial lines must also be given to Eusebio A. Morales, secretary of the treasury.

Test of Friction Losses Made on Large Penstocks

Ideal Arrangement for an Accurate Measurement of Large Quantities of Water—Tests of Friction Losses in Tunnel

Summary of a paper on Tunnel and Penstock Friction Tests, Pit No. 1 Hydro-electric Development, presented at the P.C.E.A. Convention, June, 1923, by R. A. Monroe, Department of Engineering, Pacific Gas and Electric Co.

AN IDEAL opportunity to make an accurate determination of pressure tunnel and penstock friction losses is offered by the arrangement of the Pit No. 1 Development of the Pacific Gas and Electric Co., particularly as two parallel penstock lines afford a ready means of measuring the penstock friction, and an accurate measurement of the large quantities of water utilized is afforded by a standard weir located at the lower end of the stilling basin in the power house tail-race. The upper portion of Pit No. 1 penstock is composed

LOCATION OF PENSTOCK AND WEIR GAGES

of butt strap riveted pipe, and the lower portion of lap-welded bump-joint pipe so that it is possible to obtain a direct comparison of the loss in these types of pipe.

The conduit for Pit No. 1 power house consists of about 1,000 ft. of open canal, 10,160 ft. of concrete lined pressure tunnel and 1,372 ft. of steel penstock. The tunnel is connected to the penstocks by a surge chamber which consists of a circular well 60 ft. in diameter and over 60 ft. in depth designed to serve also as a spillway. The water after passing through the turbines is discharged into a stilling basin and measured over a weir before passing through the tail canal into the Pit River.

Tunnel Friction Tests—The tunnel is of horseshoe section 14 ft. 3 in. high by 13 ft. wide and has an area of 156 sq. ft. and a hydraulic radius of 3.42 ft. At a point about 1,000 ft. from the upper portal, there is an angle of 36 deg. From this point to the surge chamber the tunnel is on tangent. The section for 400 ft. from the surge chamber is circular with a diameter of 14 ft. having a flaring section where it enters the surge chamber.

The surface of the tunnel lining is not particularly smooth and even. Wood forms coated with oil when first constructed

were used for the side walls and roof. After the forms were stripped, the rough patches and stone pockets were plastered over and the entire area brushed over with a neat cement grout which resulted in a smooth, almost glazed finish. Ordinarily, the alignment of forms was very good, and in cases where excessive offsets occurred they were chipped off. The invert was placed by hand without forms and presents a rather rough uneven appearance.

For securing the loss of head in the tunnel, the difference in water level between the intake canal at the tunnel portal and the surge chamber was taken. The water surface elevation at the intake was obtained from a staff gage fastened to the vertical wall of the portal structure immediately above the grizzly. At the outlet portal of the tunnel the surge chamber served as a huge manometer in which all small fluctuations were damped and close readings were made possible by an attached water gage. These gages were set on U.S.G.S. datum to read actual water elevations.

The loss of head in the tunnel was determined by a simultaneous reading of the gates at the intake and surge chamber after steady flow conditions had been established. For the lower flows the excess water in the river was turned out at the intake dam so that no spill existed at the surge chamber. The water level at each end of the tunnel oscillated for a considerable period after any change in flow, and it was necessary to hold a steady load at the power house for an hour or more before steady conditions were obtained. The discharge was measured by the weir for quantities up to 1,000 sec.-ft., and by current meter measurements in the intake canal for larger flows when the weir became submerged.

The computations of tunnel friction are based on the assumption that the head loss in entrance is balanced by the regained velocity head at the surge chamber and that the balance of the velocity head is lost in the surge chamber or is carried into the penstocks. This assumption may not be correct but the resulting error in any case is negligible. Data and results are as follows:

Flow	729 sec.-ft.	Kutter's coefficient $n = .0130$
"	997 "	" $n = .0128$
"	1,280 "	" $n = .0126$

Mean = .0128

The tunnel was designed on a basis of $n = .014$, which has proved conservative.

Penstock Friction Tests—The Pit No. 1 penstocks consist of two lines of pipe, each composed roughly as follows:

281 ft. of 10 ft. 9 in. diameter triple riveted butt joint steel pipe;

532 ft. of 9 ft. diameter lap-welded bump-joint steel pipe;

433 ft. of 8 ft. diameter lap-welded bump-joint steel pipe

These sections of pipe are connected by taper sections averaging about 30 ft. in length, the entire length of the penstock being 1,372 ft.

There are no horizontal angles in the penstock except at the entrance to the powerhouse tunnel where the two pipes diverge slightly. There are five vertical angles, averaging about 20 deg. each, two being in the 9 ft. diameter bump-joint pipe and three in the 8 ft. diameter bump-joint pipe.

The penstock friction tests were made by means of a differential U-tube gage connecting the two pipe lines one of which was idle and the other under flow. One arm of the U-tube was connected to the idle penstock, this arm being under static pressure, while the pressure on the other arm was reduced by the velocity and entrance head and the loss due to overcoming friction. The deflection of the U-tube multiplied by the difference in specific gravity between the water and the mercury gave directly the reduction in pressure from static in the operating pipe at the point of observation, the difference in deflections of the mercury column between any two gage boards being a measure of the head lost in that section of the pipe.

Each penstock was drilled at six correspondingly opposite points throughout its length and tapped for $\frac{1}{2}$ in. piezometer connection. The points were selected to be as near as possible to the upper and lower ends of each diameter of pipe. The upper point, 1, was placed directly below the top penstock anchor. The next two points, 2 and 3, were placed

DETAILS OF PENSTOCK JOINTS

above and below the 10 ft. 9 in. to 9 ft. 0 in. taper respectively. Points 4 and 5 were placed above and below the 9 ft. to 8 ft. taper respectively. Point 6 was placed near the lower end of the 8 ft. diameter pipe.

Before starting the penstock tests, water was allowed to run through the idle penstock for a short time in order to make sure that the temperature of the water in both penstocks was the same and avoid the necessity of correcting for temperature. The operating machine was then brought to a steady load and held there until uniform flow conditions were established throughout. Before making a series of readings, dead water and air in the pipe connections were blown out through the pet cocks on the gage boards and the surge in the penstock was throttled by the needle valve in the steam gage fitting at the top of the board. The position of the mercury meniscus on each arm of the U-tubes was read and recorded. From four to five readings at intervals from 1 to 2 minutes were made at each station, the time of each reading being recorded. It was found that by throttling the surge with the needle valve the U-tube deflections could be estimated to thousandths of a foot. A signal

LOSS IN SECTIONS OF PENSTOCK FOR VARIOUS FLOWS ASSUMING VALUES OF "N" IN KUTTER'S FORMULA

system was used so that the recorded deflections for each were made simultaneously. Both weir hook gages were read at approximately 5-min. intervals throughout the test, and the electrical output of the generators also served as a check on the quantity of water measured.

Two series of penstock tests were made, one with the generator carrying full load under a flow of 982 sec.-ft. and one with three-quarters load and a flow of 714 sec.-ft.

Tap 5 on the penstock had been placed within 9 in. of a bump joint and the deflections at this point were all in excess of what they should have been on the basis of the velocity head loss through the taper between gages 4 and 5, plus the friction loss in this distance, based on the value of "n" in Kutter's formula as determined in the 9-ft. diameter section.

A check on the measurements of friction loss for the several sections of pipe is afforded by the loss in head for the entire line as indicated by the power house pressure gage

DIFFERENCE IN ELEVATION BETWEEN TUNNEL PORTALS FOR VARIOUS FLOWS AND VALUES OF "N"

readings, there being one such gage on each penstock. This check is extremely rough, an error of a foot or more being quite possible due to the coarseness of graduation and the vibration of the indicating needle. The results were:

Flow Sec.-Ft.	Friction Coefficient	10 Ft. 9 In. Riv. Pipe	9-Ft. Bump Joint	8-Ft. Bump Joint
714	Kutter's "n"...	0 0128	0 0131	0 0127
	Williams-Hazen "C"...	120	113	115
982	Kutter's "n"...	0 0125	0 0127	0 0123
	Williams-Hazen "C"...	120	114	115

From the results obtained for the penstock pipe it would appear that the 10 ft. 9 in. diameter riveted steel pipe had a slightly lower coefficient of roughness "n" than the 9 ft. diameter lap welded bump joint pipe. The section of riveted pipe tested was of large diameter and straight between the gages while the welded pipe had two bends of about 20 deg. each in the length between the gages. No satisfactory data for loss of head in bends in large pipe are available but it is evident that for large diameters welded and riveted pipe are practically on a par as regards friction loss and that a value of $n = 0.013$ in Kutter's formula or $C = 115$ in the Williams and Hazen formula can safely be used for new pipe. The excessive U-tube deflection at Point 5 placed 9 in. from a bump joint indicates that there is considerable disturbance of the water in the vicinity of the bump joints.

Suburban Electrification at Melbourne, Australia

Multiple-Unit Electric and Steam Main-Line Trains on Same Tracks of 145-Mile 1,500-Volt D. C. System Completed in 1923—Economic Results—Quicker Service Increases Traffic and Revenue

IMPORTANT IMPROVEMENTS in train service and operating expenses have resulted from the electrification of the extensive suburban system of the Victoria Government Railways at Melbourne, Australia, which electrification was completed over the entire system early in 1923. Notable features in this new installation are the operation of suburban electric and main-line steam traffic on the same lines; the higher speed and better service at lower cost, resulting in increase in traffic and revenue; the adoption of through routing instead of having all trains terminate at the city station; and the supply of current in large quantities by the railway power plant for general power purposes. All trains have American motor, electrical and brake equipment.

This suburban system includes 145 miles of line

Sandringham, a distance of eighteen miles, and since then the work has proceeded rapidly, so that in June, 1922, about 80 per cent of the suburban traffic was operated by electric trains.

Supply of current at low prices for power purposes is an important feature of the project, since the peak demand for railway service is reached only during the short rush-hour periods of morning and evening. A steadily increasing cost of coal is a factor in the economy due to electric service. Thus the original estimates showed an economy when the price of coal was about \$2.50 per ton, but in 1919 the price had increased to \$4.60 per ton delivered at the power station. The total expenditure to June 30, 1922, was \$27,484,200, which was expected to be increased by \$3,250,000 before completion. On the other hand, some of the expenses were properly chargeable to such accounts as general power supply, line improvement and signaling, so that the final cost for electrification will be reduced accordingly.

Economic Results of Electrification—In the annual report of the Victorian Railways Commissioners for the year ending June 30, 1922, the results obtained were presented as follows:

A marked increase in business has resulted from the electrification of the various lines. The economic efficiency of electric train operation compared with steam locomotive working has made possible an average increase of about 35 per cent, as compared with the previous steam train time-tables, in the total number of trains scheduled, the cost of which under steam traction would have been prohibitive. The fast and frequent electric train service now provided during the slack hours has encouraged considerable additional traffic. On 95 miles of electrified line, out of a total of 145 miles, the extra traffic due to electrification (after allowing for the normal expansion that would probably have occurred had steam traction continued and for other factors) is valued at approximately \$850,000 per annum, while the increase in the number of passenger journeys is estimated at 12½ per cent. Present indications are that the annual interest on the scheme will be offset by the increased traffic induced through the improved train service afforded by electrification.

Local or Wonthaggi slack coal is utilized at the Newport power house for the generation of electricity, and the use of this cheaper grade of fuel and the elimination of steam locomotives from the suburban system have enabled considerable savings to be effected in the cost of train operation. It is estimated that to run the present electric train mileage under steam conditions would require approximately double the quantity of coal now consumed at the power house to generate current for train operation. In addition the coal for locomotives would require to be of higher quality and would be relatively more expensive, while the advantages of the higher speed and the greater flexibility of the electric train would not be available under steam.

An important advantage of the electrification scheme is that it has enabled the central station at Flinders St. to be used largely as a through station instead of a terminal, and has deferred costly duplications of tracks and the provision of other facilities which would have involved expenditures amounting to several million pounds. If electrification had not been adopted, a large outlay would have been required for new locomotives and additional carriages to operate the suburban train services; and even then the great improvements in speed and frequency afforded under electrification would not have been practicable had steam working been continued.

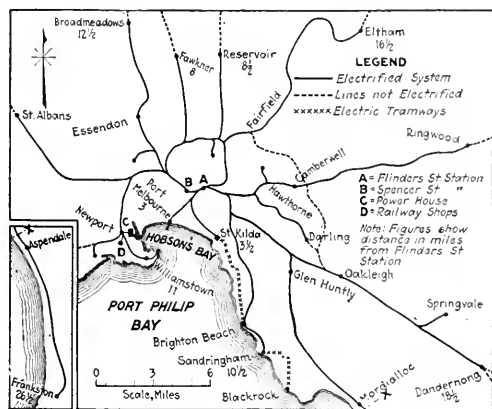

FIG. 1.—ELECTRIFIED SUBURBAN LINES AT MELBOURNE, AUSTRALIA

with 346 miles of track. From the map, Fig. 1, it will be seen that the system consists of a number of radiating lines which extend through numerous residential districts and to a maximum distance of 26 miles from the central passenger station at Flinders St. There are about 2,376 electric suburban trains daily in and out of this station and approximately 240,000 passengers are handled daily. With main line and freight trains the total daily traffic at Flinders St. is about 2,640 trains. Electric traction is only for the suburban traffic; main-line trains will continue to be operated by steam locomotives over the electrified portions of the railways, but main-line electrification is being considered by the Railway Commissioners.

Electrification of the suburban service was authorized in 1912, when the traffic had developed to such an extent as to necessitate either additional tracks to increase the capacity for steam traction or a change to electric traction to increase the traffic capacity of the existing tracks. Contracts were let and work was commenced in 1913, but war conditions caused protracted delay and increased the cost considerably. The first electric train was run in May, 1919, between Essendon and

The original project of establishing a railway traction scheme has developed in another highly important direction, namely, the supply of power for industrial purposes. The total monthly output from the Newport power house is now approximately 14,770,000 units, of which 6,400,000 units are being sold for other than railway purposes.

Electric System and Power Station—A 1,500-volt direct-current system was adopted, since a comparison of alternative bids for systems using 1,500-volt direct-current and 11,000-volt single-phase alternating-current indicated that the former would be about 23 per cent lower in first cost and 22 per cent lower in annual operating expenses.

The power station of 100,000 hp. capacity is located at Newport, near the mouth of the Yarra River, an arm of Port Phillip Bay, since the requirement for condensing water is about 6,000,000 gal. per hour when working at maximum capacity. Structural steel framing is used for the building, with walls of cement plaster on expanded-metal lathing. It is U-shaped in plan, with the turbine room and switch room extending across the full width and with two boiler rooms forming the legs. A low structure between the boiler rooms contains laboratories, store rooms and locker and toilet rooms. Beyond each boiler room is a coal pile straddled by a steel trestle on which travels a locomotive crane handling a grab bucket. There is ample space for a proposed duplicate power house.

Six turbo-generators of 12,000 hp. constitute the present main power equipment, with two 350-kva. machines for starting the auxiliary apparatus when all the main turbines are shut down. Room is provided for two more generating units. Steam is supplied by twenty-four water-tube boilers carrying 210-lb. pressure, each boiler room having twelve boilers in six batteries on opposite sides of a central firing room, with a low smokestack to each battery.

Coal from 15-ton drop-bottom cars is dumped into a track hopper and after passing through crushers is fed to bucket conveyors which deliver it to overhead bunkers of 3,000 tons total capacity or to the coal storage yard. This storage coal is reclaimed by the locomotive crane mentioned above and delivered to conveyors for filling the bunkers. Suction conveyors remove the ashes, but narrow-gage tracks with $\frac{1}{2}$ -ton cars are provided for emergency.

Transmission Cables and Trolley Wires—Current generated at 3,300 volts is transformed to 20,000 volts for transmission to fifteen substations where it is transformed to 1,500 volts for delivery to the overhead wires. Another substation controls supply to the railway shops and two 600-volt substations provide for current supply to the St. Kilda & Brighton and Sandringham & Blackrock electric tramways (Fig. 1). In the city the transmission lines are laid mainly in trenches in the streets, owing to the limited space along the railway tracks, but in outlying districts they are carried on brackets on the poles for the overhead wires, as shown in Fig. 2.

Overhead contact wires or trolley wires are suspended from catenary cables carried by light steel bridges 300 ft. apart, with tension devices on anchor bridges at intervals of 3,000 ft. At each bridge the wires are held from swaying by horizontal arms or pull-offs attached to the posts. For curves, one pull-off is attached to a rigid vertical member depending from the bridge, as in Figs. 2 and 3. For double-track these bridges have

tapering posts composed of two 6-in. channels with web lacing and a top member consisting of two 6-in. channels with attachments for the catenary cables (Fig. 3). For more than two tracks a light horizontal truss is used, with hangers to carry the catenary cables. For long spans and the complicated wiring over station approaches, two-hinged "arch" trusses are used, having vertical side members resting on shoe pins. The largest of these "arch" bridges, shown in Fig. 3, has a span of 120 ft. and a truss depth of 7 ft., with the bottom chord 30 ft. above the rails.

Since the catenary cables serve as feeders they are electrically connected to the trolley wires at 600-ft. intervals, owing to the low conducting power of the hangers, which have a chain link connection to the wire to allow for vertical motion caused by the passage of the pantograph collectors on the motor cars. These cables are of copper for the main tracks and of galvanized steel for the side tracks and yards. At the Flinders St. station, four double-track main lines pass

FIG. 2—BRIDGE CARRYING TROLLEY WIRES AND TRANSMISSION CABLES

through the coach yard, and here the catenaries for the yard tracks are carried by transverse wires attached to the cable bridges over the main tracks.

The contact wires have a normal height of $16\frac{1}{2}$ ft. from the rails, with a maximum of 18 ft. at road crossings and a minimum of $14\frac{1}{2}$ ft. under highway bridges. This minimum gives a 4-in. clearance above the maximum limit of main-line equipment and 12-in. below the bridge structure. At low bridges the supports are placed out of the line of the blast from steam locomotives.

Track and Terminals—All tracks are of 5 ft. 3-in. gage and are spaced 11 ft. 8 in. or 12 ft. 8 in. c. to c. Track construction consists of 80-lb. and 100-lb. rails spliced with six-bolt angle-bars and spiked to hardwood ties 10x5 in. and 9 ft. long in $1\frac{1}{2}$ -in. stone ballast 10 in. deep under the ties. The tie spacing is 34 in. c. to c. or 20 in. at rail joints. These lines are mainly double-track, but with some four-track and six-track stretches and about twenty miles of single-track. The maximum grade is 2 per cent and the sharpest curves are 10 deg. on the viaduct approaching the main passenger station at

Flinders St. Transition curves are used on all sharp curves. Automatic three-position block signals of the semaphore type are used (Fig. 3).

There are two important city stations, the principal one, at Flinders St., having thirteen through tracks in alternate groups of three and two with four island platforms and two side platforms. These station tracks converge into a four-track approach at each end. A few blocks distant is the Spencer St. terminal station, with two through tracks and twelve stub tracks. All stations have high platforms. At the suburban stations the platforms are usually for six-car trains but these are being lengthened for eight and ten cars.

Train Equipment and Service—Multiple-unit trains are used for the suburban service, composed of 47-ton motor cars with and without driver's compartment and 27-ton non-motor trail cars. Each train has alternate

for the outlying portions during the busy period. Electric locomotives for the suburban freight service are proposed, as steam locomotives are wasteful of coal.

With steam operation, practically all suburban trains made the Flinders St. station a city terminal. But the service has now been improved by making through trips on electrified routes between outlying points, thus reducing the switching and delay in the city station. Such routes are from Williamstown east to Oakleigh and Glen Huntly, and from Sandringham north to Broad Meadows (Fig. 1).

Cost and Economy—The capital cost is put at about \$30,000,000, with annual costs of \$2,550,000 divided equally between operating expenses and interest. The cost has increased enormously beyond the original estimate of 1912 as a result of additions and enlargements of the original plans and also very largely due

FIG. 3—BRIDGES FOR OVERHEAD WIRING ON MELBOURNE SUBURBAN LINES
At left, automatic signal and bridge for catenary cables on double track. At right, 120-ft. two-hinged arch trusses carrying catenary cables for group of tracks.

motor cars and trailers. Six-car trains are operated ordinarily, but provision is made for longer trains. Although the cars are of 5 ft. 3 in. gage, they and their electrical equipment are so designed as to admit of a future change to the 4 ft. 8½ in. gage.

About half the cars are a combination of American and European types, having transverse seats and a center aisle, but with sliding side doors; transverse bulkheads with sliding doors divide the cars into first- and second-class sections and smoking rooms. The other cars are of the European type with transverse compartments and swinging side doors. All cars are mounted on four-wheel trucks. Their seating capacity is 80 and 84 passengers for motor cars and 90 and 94 passengers for trail cars. Each motor car has four 140-hp. motors and a pantograph collector operated by compressed air; the collector is fitted with renewable copper wearing plates filled with graphite grease.

Electric trains have been introduced gradually and steam trains correspondingly retired. An average increase of 30 per cent in speed is one result, owing largely to the rapid acceleration with electric trains, so that the time of the various trips is reduced by three to eleven minutes. The maximum speed capacity on level track is 52 m.p.h. All trains are equipped with Westinghouse brakes. A 2-minute service is operated on some of the inner lines, and from 2½- to 3-minute

to the great increase in prices following the World War. Thus the turbo-generator equipment increased 100 per cent; electrical equipment for power house, substations and cars, 80 per cent; high tension cables, 78 per cent, and overhead wiring equipment 67 per cent. Labor costs also increased 70 per cent.

On the other hand, large operating economies have been secured. In 1921, the results of five lines operated by electricity indicated a saving of \$230,000 in coal and \$250,000 in staff and rolling stock, combined with an increased revenue of \$955,000 due to better service. For that year, the power house required 54,000 tons of coal at \$350,000, while an equivalent service by steam locomotives (but at lower speed) would have required 91,000 tons at \$640,000.

This electrification was considered by the Victorian Railways Commissioners as early as 1898, and in 1908 a report was made by C. H. Merz, of London, who predicted that it would reduce operating expenses and increase traffic and revenue. Under an agreement made in 1912 the work has been planned and carried out by Merz & McLellan, consulting engineers, London, England, with E. P. Grove as their engineer in charge at Melbourne. British and Australian manufacturers supplied most of the material, but all electric equipment for the cars was furnished by the General Electric Co., New York.

Through the Reclamation Country

By F. E. Schmitt

Associate Editor, *Engineering News-Record*

A SERIES OF ARTICLES on Federal Land Reclamation is to start in *Engineering News-Record* in a few weeks. It will give a history of the twenty-one years of government irrigation, state the many problems of operation—engineering, agricultural and financial—analyze the various complaints that are being so emphasized by those who are seeking a reform of the current law and methods and seek to present some views as to a constructive policy in the future. Through it all will run the evident theme that irrigation, from planning, through construction to operation, is a continuing engineering problem.

As a part of the preparation of the series Mr. Schmitt is now traveling through the West, visiting irrigation projects, studying developments and interviewing builders, operators and settlers. He will write a series of letters of running comment on the situation as he sees it on the ground. These are not the final result of his trip but they will serve to acquaint our readers with the actualities of reclamation as revealed to an unprejudiced investigator.

This is the second letter. The first appeared in the issue of October 4.—*Editor*.

Grand Junction, Colo.

SEEN AT close range, a reclamation project in full-size operation is impressive. It is a community of many thousands of people grouped around and among the parts of a vast water-supply machine which spreads out over a hundred square miles or more. The machine must be operated: the required amount of water according to daily request or a fixed schedule of rotation must be admitted at each farmer's headgates, disputes between adjoining users about supply or overflow of water must be prevented, consumption must be measured, canals, gates and structures must be kept in order. Finally, hardest of all, payment for the water must be collected. The manager has a combined administrative, engineering and excise job of peculiar difficulty. He not only has to operate and maintain and repair his machine, but he must keep it in gear with the community. The successful manager with his water-masters and ditch-riders should know the family history of each one of his thousand or more farmers, how many cows he milks, what oil stocks he bought, whether he can pay his mortgage interest this fall, and why he is making a failure.

On the ideal reclamation project the job would be simpler—the manager would be an operating automaton with cash-register attachment. The ideal project is one on which every family is contented and happy and each farmer pays his debts, puts money in bank regularly and finally buys out his neighbor. But probably there is no such ideal project, just as there is no such community in the unirrigated world. Some men do not do as well as their neighbors; others become failures. There are quite a lot of failures on the reclamation projects (I have seen three projects so far) and the amazing part of it is that some of the failures now developing are men who have been there from the start. There are the skillful and the unskillful; the thrifty and the unthrifty. The latter kind doesn't manage to pay its debts and finds it impossible to meet the annual water charges and the installments of the construction charge which the nation advanced free of interest for twenty years. Largely the three projects are still in

process of evolution though they are up to 14 or 15 years old; and the troubles incident to evolution are quite obviously at the root of most of the complaints and protests that are heard. There is still much pioneering to be seen, which answers an advance question. The rough work and hardship of starting to farm on irrigated desert is not all of the past. It appears that the period required to catch up with the game of making a living out of the allotted farm unit is not over after two or five or fifteen years, in a great many cases.

Scores of farmers are existing in the most primitive condition, scratching for a living, in debt and getting deeper in; and hundreds have left. Some never had anything, some have lost what they had at the start. This man quit, that one was foreclosed by creditors. There are a few abandoned farms, and it will take more pioneering to get them in operating shape. Plenty of prosperous farmers can be found, men who have not only made money but have built up thriving farms. But there are the others also. The settlers pioneered when they started, and needed a chance, a breathing spell to get going. Many still need a chance.

Making successful farmers out of pioneers is a many-sided problem. Numerous trouble-making factors are involved in converting raw irrigated land into a self-supporting farm community, and there are various opinions about them. But prominent among them are two facts which are early apparent, namely, that there is much poor land on the projects and many bad farmers. Some people say that "the bad farmer is found on the poor land." And a Federal Land Bank man whom I met said "that is where we get the majority of our loan applications." Nevertheless the two facts are separate. The poor land was there before the settlers came and the bad farmer was not made such by the land.

These facts are probably commonplaces to men in the irrigation states, but the man in the humid regions and particularly the non-farming citizen, who may have much to do with working out the future of reclamation, does not think of them as important factors. It may be that commonplaces of this kind make up the main part of the problem of operating reclamation successfully.

What To Do With Poor Land—First as to poor land. A reclamation project area includes both smooth and rough ground, flat and steep (or rolling) topography, good soil and poor soil; it may have areas of hard clay or troublesome zones of drifting sand. There are acres of ground that are practically non-arable. In some cases the settlers in a poor district were allotted larger areas than those in the good. But with this exception, all farmers on a project are on equal terms: they pay the same for water (annual charge for operation and maintenance) and they are expected to pay the same per-acre share of the original cost of the works (construction charge). Their taxes may be slightly lower because of lower valuation.

Most of the farmers on the poor land are just hanging on. It was poor land originally, and much of it should never have been included in the reclamation. This last was stated positively by an agricultural expert whom I met on one of the projects and was supported by other men of almost equal qualifications. On some projects much land has been injured by alkali or waterlogging (seepage) troubles not yet cured, but that

is not in question now; there is poor land today that was poor at the start, and it would have been well if engineers and soil experts working together had kept it out of the reclamation.

Why they did not seems to be a somewhat complicated question. The original reclamation law as interpreted by executive officials left the land open for homestead entry while the irrigation works were being built; the result was that on early projects good and poor land was taken up by settlers in the definite expectation of obtaining water, and it would not have been practicable later on to refuse to supply the men who had been unwise or unlucky enough to settle on poor land. Co-operation between soil experts and engineers did not go far enough, according to our present lights. Knowledge of soils was imperfect, and knowledge of irrigation agriculture was imperfect. The Department of Agriculture has maintained a dozen or so experiment stations on the projects for many years, and is still learning something about cultural and soil questions. In fact, successful irrigation farming seems to involve not only more labor and a different skill from that demanded by ordinary farming, but a somewhat different science, which is only partly worked out as yet.

Remedies—Unwise inclusion of poor land is chargeable to a number of agencies, among whom the engineer is bound to take his share of blame. However, the question today is not who was at fault, but what to do about the poor land—how to prevent continuing failures on it, with steady trouble and expense to the country at large, the local community and the settlers. Two lines of thought are being followed in this matter.

One involves classification of all land on a project into good, less good, etc., and adjustment of the terms of repayment accordingly. Such classification has been carried out on a few projects (notably on the North Platte), by varying methods, but apparently has not yet been put to use. The share of construction cost on the poor land could be lowered, but that on the good land cannot be raised because the farmer holds a contract which limits the amount he must repay. The time allowed for repayment might be varied, a longer period being fixed for poor land than for good; but the repayment period is laid down in the law by Congress, and at present is alike for all. On future projects it would seem quite possible to grade the construction charge according to land quality. On the existing projects—those which because of poor land are not doing as well as they should—it may be necessary for Congress to authorize extensive readjustments of burdens according to land quality.

The worst of the land ought to be abandoned—this again in the judgment of agricultural men who have watched the farmers' results. Where land is so rough that proper leveling is unduly costly for the settler, so that he is likely to use inefficient irrigation methods or be seriously hampered in getting under way, the advisability of doing some leveling at government cost suggests itself; but on this last subject decided differences of opinion exist.

Paternalistic Suggestions—The other way proposed for dealing with poor land is based on developing the right farming methods for such land (readjusting the size of the farms to suit, where necessary) and teaching these methods to the farmers, with the help of some means of insisting that they adopt them—if such

means can be found. This is also a method proposed for dealing with the bad farmer, namely, to make him into a good farmer rather than let him go to the dogs. In either light, such an instructing and assisting process would require a large organization and a strongly administered agricultural purpose on the part of the government, neither of which exists. The Reclamation Bureau is not an agricultural organization and is said to have no authority to use the reclamation fund for such work, while the Department of Agriculture appears to have no recognized responsibility for the success of the reclamation projects, besides having no funds. On the other hand, the states in which the projects are located seem to find plenty of troubles of their own without bothering much about nursing the irrigation communities; that is Uncle Sam's business! County agents and state experiment and demonstration work help a little, but they do not go far toward reaching the incompetent farmer.

With reference to the bad farmer: while some people want him to be advised and helped, others would eliminate him just as early as possible. They claim that unskilled farmers—ex-school-teachers, bookkeepers or dentists—have no more business on a reclamation project, where the nation has invested much money, than a farmer has in dentistry or teaching. They want to select the men who go on the projects and accept as settlers only able, strong, experienced farmers with ample money and credit.

The underlying idea of such selection of course would deny the right of trying to found a farm home in the West to all except those few who could meet certain tests or inquiries. People who are not ready to admit that selection in advance is feasible or desirable say that there should be automatic selection, by practical trial; let the fittest survive! Those farmers that fail to make a success, fall behind on water and construction payments and are short of credit at the bank, should be closed out and the successful farmers alone be retained—with special treatment for the occasional farmer whose bad luck is not his fault. Stated this way, the process seems a little cold-bloodedly business-like, particularly if the unsuccessful farmer has been handicapped by poor land. But it is the method which is necessarily applied on all private irrigation projects and which operated in all the farm pioneering that has gone on from the earliest days; and it is the method of every other business and occupation besides.

Reorganization of Alsace-Lorraine Railways

One of the more difficult of the problems of adjustment which the French Parliament is called on to solve as the result of the re-incorporation of Alsace-Lorraine into French territory is the relation of the Alsace-Lorraine railroads to the French railroad legislation. The possibility of operating the Alsace-Lorraine railroads directly by the state was at one time considered, but rejected. By a plan now advocated the Alsace-Lorraine railroads will be operated by the *Compagnie de l'Est*, but upon a special account and under the direction of an office located at Strasbourg. The proposed plan also provides that the three Departments of the restored provinces shall be represented on the Railroad Council (*Conseil des Chemins de Fer*). Employees will retain all rights which they have earned and the special features of the railroad operations, such as fourth-class tickets, Sunday tickets, etc., will be conserved.

New Logarithmic Equation for Friction Losses in Pipes

By F. W. GREVE

Associate Professor of Hydraulic Engineering,
Purdue University, Lafayette, Ind.

AMONG the large number of formulas available for the determination of friction losses in pipes, those of the exponential type possess the greatest advantage. All of them, no matter what the type may be, depend upon coefficients which vary with the diameter and length of pipe, velocity of flow, etc. The formula herein described has been devised with the aim of reducing the number of variables to a minimum. The basic equation for its derivation is,

$$h_f = A(v)^B \quad (1)$$

where h_f is the friction head, or the head lost due to friction in 1,000 ft. of iron pipe, A is a coefficient dependent upon the diameter of the pipe, and B is a constant exponent for all diameters. The coefficient A may be expressed in terms of two other constants, E and F , thus enabling computations to be made without reference to book or tables.

The formula (1) is empirically derived from the plotting of the logarithm of the friction head against the logarithm of the velocity on rectilinear cross-section paper, or, better yet, the derivation of the ratio of these two quantities when plotted on logarithmic paper. The

coefficient, A , from the equation, the values of A were plotted vertically against the diameter, d , on logarithmic paper, the graph resulting therefrom being a straight line of the form,

$$A = E(d)^F \quad (2)$$

where E is a constant coefficient; d is the nominal diameter of the pipe in inches; and F is the tangent of the angle that the graph makes with the d axis. The value of F is negative, showing that the graph extends from the upper left towards the lower right of the diagram; or that the value of A decreases with increase of d . Combining equations 1 and 2, there will result,

$$h_f = E(d)^F(v)^B = 10.96(d)^{-1.169}(v)^{1.85} \quad (3)$$

$$\log h_f = 1.03995 - 1.169 \log d + 1.85 \log v \quad (4)$$

Thus for any iron pipe, the friction head per 1,000 ft. of length can be expressed in terms of one variable, namely the velocity. Besides the advantage of simplicity and ready adaptation to accurate plotting, the exponential equation cited above eliminates the necessity of resorting to the cut and try method of solution, as exemplified in the commonly used formula,

$$h_f = \frac{fL(v)^2}{2gd}$$

where the velocity or the discharge is to be calculated.

German Labor in French Building Trades

Paris Correspondence

A FACT generally recognized is the shortage of many kinds of labor in France, in mines, in railway construction, in agriculture, notably in masonry and in the building trades in general.

An interesting experiment has been made during the past eighteen months or so in the Liberated Regions of North France by the employment in the building trades of German labor under conditions which if they do not bespeak a wholly liberal interpretation of the relations of the employer and the employee have at least produced interesting results on both sides.

In the region of Montdidier the Société Parisienne d'Enterprises has employed eighty German workmen recruited through the labor bureau of Treves, but only after serious investigations as to the sentiments, honesty and capacity of the workers in question. Of this number thirty were ultimately rejected as undesirable and the fifty remaining, divided into two groups, have been employed on construction and building jobs at the trades of masons, plasterers and tile workers. Invariably they have produced satisfactory results, as well from their deportment in a lately invaded country and for the quantity and the quality of the work they have turned out. Their pay has ranged from 35 to 40 francs a day (at normal dollar exchange, \$7 to \$8) of which 10 francs is paid the contractor for their food and lodging.

An impartial estimate of the worth of this labor, which was recruited from the Rhineland provinces, was made by the consulting architects and it was considered that it produced results which were technically excellent and rapid. Their relations with the neighboring populations were invariably correct, no complaints having been made at any time. They worked chiefly under orders which were passed to them by a Swiss engineer trained in the construction trades and speaking French and German. In summing up it is the opinion of the French government labor bureau that the experience had given most satisfying results.

VARIATION OF THE COEFFICIENT, A, WITH THE DIAMETER, d						
d, in.	1.0	1.25	1.5	2.0	2.5	3.0
A	10.4	7.49	6.22	4.86	3.76	3.03
d, in.	4	5	6	8	10	12
A	2.15	1.70	1.34	0.960	0.757	0.597
d, in.	16	20	24	30	36	42
A	0.429	0.330	0.267	0.204	0.166	0.140
d, in.	48	54	60	66	72
A	0.119	0.104	0.0917	0.0819	0.0744

graph is a straight line when plotted on logarithmic paper, and since its position is determined by three points it is only necessary to plot the minimum number of values of friction head and velocity. An easy mathematical solution for this latter graph is by the centroid method. The centroid of all the plotted points is first obtained by finding the mean values of friction head and velocity. The points on either side of this centroid are then treated in a like manner to locate their respective centroids, thus determining three points that establish the straight-line graph. A graphical check is readily applied by measuring the slope B , with the velocities plotted as the abscissas, and ascertaining the value of the coefficient A , which is the value of the friction head for a velocity of 1 ft. per second.

The values of the various constants noted in this article are based to a large extent on Williams and Hazen's "Hydraulic Tables," and have to do with iron pipes that have been in use for moderate periods of time.

The values of A and B listed in the accompanying table were first obtained as previously outlined. The exponent B is a constant and equal to 1.85 for all sizes of pipe under consideration. The accuracy obtained with a fixed value of B is well within practical limits, for no two pieces of pipe, even when new, show exactly the same friction head for a given velocity.

The formula, $h_f = A(v)^B$, is simple and easily manipulated with the aid of the accompanying table, which shows the variation of A with the nominal diameter in inches. With the idea of eliminating the variable

Hints That Cut Cost and Time

For the Contractor and the Engineer

Designing Steel Details With Attention to Drainage

BY ARTHUR M. SHAW
Consulting Engineer, New Orleans

WHILE it is generally recognized that structural steel, exposed to moisture and atmospheric action, is susceptible to rapid corrosion, an examination of many bridges and other steel structures would convince an observer that it is still pertinent occasionally to suggest that more attention be given to the design of details in order that complete drainage may be effected, if this be possible. The accompanying photograph (Fig. 1) well illustrates the result of failure to provide such drainage.

The steel members shown consist of two 3-in. standard angles placed as corner protections to the concrete slot for receiving sliding canal gates at the end of a flume. Shortly after the flume was placed in operation (about eight years ago), the system of control was changed and the gates were discarded, thus making it unnecessary to afford any protection to the angles shown.

It will be noted that the photograph shows that one of the angles appears to be in good condition while the angle at the opposite side of the opening has lost practically its entire effective section by corrosion. The 6-in. scale lying across the opening will give an idea of proportions. The sketch (Fig. 2) shows these angles in section as "Angle A" and "Angle B," respectively. It is shown that each of these angles is tipped slightly from the vertical, to conform to the inclined position of the sliding gates, angle A being in such a position that it drains readily, while the back edge of angle B is depressed about $\frac{3}{8}$ in. below the level of the concrete work, forming a water trap from which no outlet was provided. Not only was the top leg of angle B destroyed for a considerable portion of its length but the

FIG. 1—STEEL CORRODED BY LACK OF DRAINAGE

FIG. 2—ANGLE SECTIONS SHOWN IN FIG. 1

vertical leg was so corroded as to retain no material structural strength.

In the structure shown, there were three pairs of angles, all similarly placed. In no case did the drained angles show any material reduction in section and in no case did the undrained angles fail to show a sufficient reduction in section as to render them unfit for any useful purpose, though the central section (shown in the photograph) was the most extreme example of destruction.

How One State Aids Contractors in Locating Road Materials

BY G. H. HENDERSON
Office Engineer, State Board of Public Roads,
Providence, R. I.

IN ADDITION to the standard plans and specifications at the disposal of prospective road bidders, it is the practice in Rhode Island to furnish the contractors with all the information at our disposal concerning the availability of local materials, such as sand, gravel and stone purposed to be used in the proposed construction.

On the quantity sheet of the standard plans, as is customary, are given summaries of the cuts and fills between stations, the locations and quantities of foundations, pipes, catch basins, guard rail, masonry etc. The quantity appearing in the proposal form opposite each item agrees approximately with the quantity appearing upon the quantity sheet of the plans.

The purpose of the material survey is not to render unnecessary personal search by the contractor for suitable material for the job, but to aid him in his search. It calls to his attention certain sources within reasonable distance of the job where materials passing specifications may be obtained, and the approximate quantity available. It saves him unnecessary investigation of certain gravel banks or sand pits which are known from tests to be of inferior quality, or which fail to pass the specifications in other respects. Further information is given such as owner's names, their willingness to sell, length and character of haul and water facilities. There is no guarantee on the part of the state that the banks will run true throughout as per the samples taken and tested. The state does not own any banks nor is there any law which permits it to purchase.

The information for the material survey is obtained by a material survey force working under direction of our testing engineer, who also has charge of our testing laboratory. The force consists of a nucleus of two men regularly employed in this work and is augmented from time to time by men from other departments of our work. Material survey work is practically continuous and will be until the whole state has been covered. It is our policy to use men in this work who are temporarily out of employment in their regular capacity. Resident engineers and assistants at the completion of a contract and until construction work resumes, either join the material survey force or are used to augment

Location—Station 250 approx. Left Sec. IV.

Accessibility—0.7 mi. west of State Road on narrow gravel road, easy grades.

Description—Large bank, approx. 10,000 cu.yd., containing large quantity of heavy gravel. Six-foot to 9-ft. face under 12 to 18 in. loam. Coarse aggregate 40 per cent to 80 per cent over $\frac{1}{2}$ in. up to one-man size.

Conclusions—Samples of sand and stone passed all requirements for gravel foundations, and cement concrete specifications.

Steam Shovel Places Heavy Water Pipe

IN THE construction of a dam for the Tipton Water Co. in the mountains near Tipton, Pa., the contractor had to place a line of 36-in. cast-iron pipe and also one of 24-in. pipe. The method used is shown in the illustration. The pipe was brought in on the narrow-gauge railroad at the left. Lengths were picked up by the shovel and swung to place. The shovel moved ahead as each length of pipe was set so as to be in position to place the next length. A considerable saving of time and labor was gained. A. L. Anderson & Brothers, Inc., of Altoona, Pa., is the contractor with A. F. Ponesmith superintendent in charge of the work.

Low-Water Bridge Built in Kansas

BY CHARLES O. BOYNTON

County Engineer, Gove County, Kansas

IN PARTS of western Kansas, in common with many other similar localities, where grazing land predominates and where the rainfall is insufficient for general farming, the funds available for roads and bridges are very limited. The Kansas law limits the mileage of county roads in the western part of the state to about 150 miles, the minor roads being designated as township roads and maintained by the township officials. The funds available for the county roads

From Job and Office

Hints that Cut Cost and Time

amount to a little more than \$100 per mile for construction and maintenance and from this money must also be built culverts and bridges on township roads where the span is in excess of 5 ft.

Except during seasons of unusually heavy rainfall, the streams are generally dry. Then, when it does rain heavily, the rise is sudden but the crest soon subsides. This characteristic, coupled with the light traffic and insufficient funds, has caused the "low-water" crossing to be much used in preference to the ordinary bridge. The low-water crossing is designated so that the opening below the floor is sufficient to pass the ordinary low water flow while the high-water level may be considerably above the floor level. The short interruptions to the light traffic at times of occasional floods do not justify the additional expense of regular bridges.

The accompanying drawing shows a low-water crossing recently completed by Gove County. It is estimated that the ordinary high-water discharge will seldom exceed 500 cu.ft. per second, although occasional floods will greatly exceed this amount. The flood peak in excess of the 500 sec.-ft. would last but a very short time, a few hours only, and probably do but little damage to the approaches. The 10-ft. opening is ample for the ordinary low-water flow. Walls extending out from the culvert 25 ft. in each direction along the downstream side of the roadway fill act as dams or retaining walls to hold the fill. They are set into the bedded shale. Their top rises gradually from the floor level 2 ft. to their ends, thus forming a notched spillway 62 ft. in length. A short apron is provided, but the water cushion at times of flood is relied upon to prevent undercutting. The gravel roadway is not expected to scour.

This structure contained 30 cu.yd. of reinforced concrete and was built by force account for \$575, including the excavation but not including the filling or the overhead expense. A reinforced-concrete high-water bridge would have cost about twice as much. This crossing was built on one of the township roads and replaces a culvert having sidewalls supporting a wood floor, the approaches to which have washed away several times.

The new structure was designed and built by Charles O. Boynton as county engineer.

LOW-COST BRIDGE FOR LOW-WATER CROSSING ON TOWNSHIP ROAD IN KANSAS

Irregular Areas in Yardage Problems Solved by Geometry

BY J. R. JAHN

Irrigation Engineer, Berkeley, Calif.

TO compute yardage in canal or levee work the following method can be used to advantage. For single computations a pair of triangles and a pencil will give the solution in the time usually taken to check the planimeter or figure out the area constant for the scales used.

It is convenient to plot the cross-section on profile paper and any convenient scales for the horizontal or vertical distances can be used. If plate "A" paper is used these scales are $\frac{1}{2}$ in. horizontal = 5 ft., and $\frac{1}{2}$ in. vertical = 1 ft. In their proper positions draw the sub-grade and sides or banks. The inclosed polygon will then represent the area in the cross-section of the cut or the fill at the given station. The volume may be found by the pyramidal formula or by simple multiplication, if the area of cross-section be known.

Fig. 1 gives the "key" to the solution: the base of the cut being given zero width for simplicity in this case. a , b and c are points on the ground surface and the area (abc) is desired.

Produce oa ; draw ab parallel to ac ; connect a and c . The triangle (aa_1c) has been substituted for the triangle (abc) and has an equal area since the base ac and the altitude of the triangles are the same. Since oa_1 is a straight line, the triangle (oa_1c) has the same area as the polygon ($oabc$). If now, y be the intersection of the ordinate or vertical from o with the line a_1c , the distance oy can be read on the profile scale. Likewise the horizontal distance a_1c_x may be found.

The area oa_1c is then $\frac{1}{2}(oy)(a_1c_x)$. (See triangles oya_1 and oyc .)

In Fig. 2, cd is the base of the proposed cut and da and cb are the banks or sides, the slopes conforming to the distorted scales used. In addition to the transformation of the cross-section of the ground surface into a straight line, the triangle (oa_1b) is substituted for the trapezium ($abcd$) by drawing a line through d parallel to a_1c to intersect bc produced. The area is again $\frac{1}{2}(oy)(a_1b_x)$.

Fig. 3 shows the method applied to levee estimates.

COMPUTATION OF AREAS BY METHOD OF REDUCING POLYGON TO EQUIVALENT TRIANGLE

As many sides $abc \dots$ as desired can be used. The problem then consists of substituting single lines for pairs until the polygon is reduced to a triangle.

I have found this method very useful in getting a quick check on the approximate area of parcels of land, mapped to scale and the accuracy is often surprising. A little ingenuity is required in order to keep the figure within the bounds of the drawing. The area of the resulting triangle is found by multiplying the scaled base and altitude and taking one half the product.

Houses Barged Across Kanawha River

TO MAKE room for the new state capitol at Charleston, W. Va., a whole community, comprising 32 houses, was barged across the Kanawha River by John Eichleay, Jr., Co., of Pittsburgh. The houses were set upon blocking 40 ft. above barge floors.

Drainage Across Side Roads

In carrying drainage of a road side ditch across intersecting roads ordinary practice in placing culverts is to install them on the line of the side ditch of the main road. One disadvantage of this practice is that the width of the side road often determines the length of culverts to be used. If this culvert, which is the exact width of the intersecting road, be laid as indicated above, it necessitates too sharp a turn from the side road into the main road or vice versa. Charles O. Boynton, county engineer at Gove, Kan., has established a practice of placing the culvert across the side road back from the side ditch line of the main road about 15 ft., thereby permitting an entrance curve from the side road to the main road and affording a much better turn.

Concrete Shed Protects Railroad Track from Mud Slides

ALONG the upper reaches of the Sacramento River in California the Southern Pacific R.R. traverses a canyon in which mud slides have been troublesome. The slides were so frequent at the point where the track enters the east end of Tunnel 9 that a reinforced-concrete shed was built somewhat similar to a timber snowshed, but strong enough to carry a load of mud and

"MUD SHED" PROTECTING PORTAL OF TUNNEL

rock. The outer wall, as shown in the accompanying picture, has openings which aid in ventilation and avoid entirely closing off the passenger's view.

Formula for Parabolic Railway Curves

BY L. PIÉARD

Draftsman, Canadian Pacific Ry., Winnipeg

FOR computing the length of vertical parabolic curves and the largest offset midway between the ends, railroad engineers in Canada are using a formula briefly stated as follows:

Having selected the rate of change (usually 0.05 for

DIAGRAM FOR COMPUTING PARABOLIC CURVE

From Job and Office

Hints that Cut Cost and Time

sags and 0.10 for summits, in railroad work), the length of the curve in stations (100 ft.) is found by dividing the algebraic difference in grades by the rate of change. This gives the E.C. and E.C., the P.I. of tangents to a parabola being equidistant from the points of tangency. The offsets equal one-half the rate of change multiplied by the square of the distance (in stations) between point of offset and point of curve.

Referring to the formula for vertical curves suggested by Stanley J. Nichols in *Engineering News-Record*, Sept. 13, p. 443, using the grades given in that example and the rate of change as 2.0, we would then have the following:

P.I. is at Sta. 11 + 00

$$\text{Length of curve} = \frac{4 - (-1)}{2}$$

$$= 2.5 \text{ Sta.} = 250 \text{ ft.} \left\{ \begin{array}{l} \text{B.C. at Sta. } 9 + 75 \\ \text{E.C. at Sta. } 12 + 25 \end{array} \right.$$

$$\text{First offset at Sta. } 10 = \frac{2}{2} \times$$

$$\left(\frac{25}{100} \right)^2 = 1 \times \left(\frac{1}{4} \right)^2 = 0.0625$$

$$\text{Second offset} = 0.0625 \times 2^2 = 0.25$$

$$\text{Third offset} = 0.0625 \times 3^2 = 0.5625$$

$$\text{Fourth offset} = 0.0625 \times 4^2 = 1.0$$

$$\text{Fifth offset} = 0.0625 \times 5^2 = 1.5625$$

Offsets taken from E.C. as starting point will have the same values as those taken from B.C.

Jet Aids in Sluicing Material Delivered to Fill on Pier

THE INNER deck floors of the transit sheds in the Ballantyne Pier at Vancouver, B. C., are supported on a gravel fill retained on one side by concrete sheet-piling and on the other side by a retaining wall. Gravel for the fill was brought to the job on barges and some study was given to the question of the cheapest method of lifting the material from the barges and

SLUICING GRAVEL DOWN A FLUME INTO FILL

From Job and Office

For Contractor and Engineer

delivering it to the fill across the 100-ft. width of pier already decked over.

An aid in finding an easy method was the 10-in. water main down the center of the pier that was used to operate the water jets in sinking cylinders through hard material, and from which some water could be spared without overtaxing the pumps. At the outer side of the pier a hopper was erected and from it a flume was built to the area to be filled, 100 to 150 ft. distant. The gravel was clammed from the barge into the hopper by means of a floating derrick and a 3-in. pipe discharged continuously at the bottom of the hopper, the jet being directed down the flume. This arrangement was described in *Engineering News-Record*, Sept. 13, 1923, p. 440. Some 5,000 cu.yd. was placed by this method, which was developed by the Northern Construction Co. of Vancouver, of which William Smail is chief engineer.

Street Widened by Moving Concrete Curb and Gutter Sections

BY J. D. ADAMS

Secretary, Engineers Club of Sioux City

PUT to an enormous expense of widening over sixteen blocks of streets to care for the increasing traffic, City Engineer L. J. Hintgen of Sioux City, Iowa, devised every possible means of saving money. One of the stunts was the setting back of a curb and gutter unit. When the curb and gutter were placed several years ago the expansion joints were made entirely through the concrete, making each section a distinct unit. A force of men with crowbars succeeded in moving the sections very rapidly.

The work was done on a contract at 34 cents a foot. The bid on new curb without the gutter was 53 cents. Thus a saving of 24 cents a foot besides a 2-ft. strip of gutter was made. There were only 600 ft. of this kind of gutter, the balance being concrete curb alone, or stones. The stone curb was moved for 29 cents a foot.

Flangeways Kept Clear of Asphalt—In paving the Bal-lantyne Pier at Vancouver, B. C., flangeways or grooves were left along the rails of the railroad tracks in the usual manner when placing the concrete. When the top dressing of asphalt was put on, however, a wooden filler was put in these grooves extending up to and covering the top of the rail. The upper surface of the filler strips was made to conform to the grade to which the asphalt was to be finished. Using this method, the black top material was dumped, spread and rolled freely without concern about the grooves. The work was therefore finished more quickly than if care had to be used to keep the flangeways clear. After the material had cooled, the wood strips were removed from the grooves and both track and pavings were ready for immediate service.

Tanks Are Built Roof First—A novel method of erection which permitted all assembling and riveting to be done on the ground was employed in building four oil storage tanks 83 ft. in diameter and 33 ft. high for the Union Petroleum Co., Belgium. The top ring was erected first, resting on supports and jacks at the ground level, the jacks being inside the tank. Then the arched ribs for the roof were placed and roof plating riveted on. Then this completed section was raised by jacks to permit the placing of the second ring, the first ring being supported on blocking and the jacks then released. There were thirty-two 5-ton jacks with lifting racks 63 in. high, the ring plates resting on the claws at the bottom of the racks and being held from slipping by vertical pins set in holes in the claws. After the last raise the lowest ring was riveted to the shell and the bottom. In raising, the foreman stood in the center of the tank and at his command the man at each jack gave a turn to the crank handle. This method is described briefly in the "*Water Tower*" by Jules Mahy, managing director of Mahy Frères, Ghent, Belgium.

Derrick Made of Standpipe Roof Trusses—In the erection of two 2,000,000-gal. standpipes 60 ft. in diameter and 100 ft. high, at Dallas Texas, construction methods were complicated by the necessity of providing a derrick high and heavy enough to place the steel plates forming the standpipe, as the usual methods of erection could not be employed. In a recent issue of *Water Tower*, published by the Chicago Bridge & Iron Works, is explained the method whereby trusses forming the conical roofs of the tanks were so detailed as to form a full-circle derrick. Sixteen of the 24 trusses forming the roof were used in assembling the mast, which was approximately 130 ft. high and 8 ft. square. The boom, 35 ft. long, was made of two trusses. There being 24 trusses to each standpipe, the derrick was located out of center so that the six remaining trusses could be raised and placed in final position before dismantling the derrick. The plates in the lower sections of the standpipe weighed 5 tons and those in the upper courses 1 ton, though the sections were each of the same size: about 7 ft. wide and 24 ft. long.

MOVING CURB AND GUTTER SECTIONS TO ALLOW FOR STREET WIDENING IN SIOUX CITY

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Grant Smith: An Appreciation

Sir—In reading over your description of work done by Grant Smith (*Engineering News-Record*, Oct. 4, p. 571) I realize how impossible it is to indicate the scope of work handled by him, or to indicate his position in the construction industry. He always avoided publicity, moved so quietly, and thought into the future to such a degree that comparatively few knew he was the head of the organization which built Shoshone Dam, removed 7,000,000 cu. yd. of earth by sluicing Denny Hill, Seattle, into the bay, and handled the removal of some 26,000,000 tons of earth in one contract for the Department of Natural Resources of the Canadian Pacific Ry. In the most active period of this latter mentioned work, which was also the most active period of the Panama Canal construction, more yardage was moved month by month in this location on the Canadian prairie than was moved in the Canal Zone.

It is probable that if statistics were prepared, it would be found Mr. Smith headed organizations which had actually constructed more miles of tunnel, more miles of railroad and moved more yards of earth, than any other person in this country.

Silent, industrious, honorable, he believed that publicity added nothing to man's achievement. He sought to carry out all his contracts according to the original intent of the agreement so completely, and his dealings with all men were so honorable, that he had a following of associates, employees and sub-contractors comparable with none in our construction history.

M. J. WHITSON,

New York, Oct. 8. Stone & Webster, Inc.

G. W. Fuller at the London Institution of Sanitary Engineers

Sir—No name is better known among water and sanitary engineers in England than that of George W. Fuller. His work is almost as well known in England as in America. It was therefore very gratifying to sanitary engineers here to know that Mr. Fuller was coming to England with the intention of reading a paper, and with the idea of improving the very friendly relations which already exist between the engineers of the two countries.

Isadore Mendelsohn, corresponding secretary of the Conference of State Sanitary Engineers, Washington, D. C., recently asked for information on the object and work of the Institution of Sanitary Engineers. His letter was sent to me, as president, and I suggested that if an American engineer would read a paper in London before the Institution, the result could not fail to be advantageous. It is further to be noted that in my presidential address of last January I drew attention to the advantage of the special consideration of methods of sanitation and drainage, having regard to American practice. There was an immediate response to this suggestion. It was expected that Prof. George C. Whipple of Harvard University would write a paper, to be presented by Mr. Fuller on a visit to London. Later on it was decided that Mr. Fuller would present a paper of his own. This resulted in a most interesting review of American Sanitary Engineering Practice, read by Mr. Fuller before a representative meeting of the Institution of Sanitary Engineers, held at the International Shipping, Engineering and Machinery Exhibition at Olympia on Sept. 10. Preceding this meeting a number of representative engineers received Mr. Fuller at lunch, among them being E. A. Sandford Fawcett and Dr. H. T. Calvert, respectively chief engineer and chief chemist of the Ministry of Health;

Prof. E. R. Matthews of the Office of Works; Prof. Henry Adams, Dr. Hele Shaw, A. J. Martin, Henry C. Adams and G. M. C. Taylor, the latter representing his father, Midgeley Taylor. Letters were received from a great many other engineers who were unable to attend, including J. D. Watson of Birmingham, H. E. Stilgoe, chief engineer of the Metropolitan Water Board, and W. J. E. Binnie.

It is certainly very desirable that the connection between engineers on both sides of the Atlantic should be strengthened. It is understood that an International Convention of Sanitary Engineers will be held at the British Empire Exhibition, which is to be opened next year at Wembley. This will be one of the largest and most important exhibitions held in the country. It is to be hoped that American engineers and scientific workers will contribute papers upon suitable subjects to be read at the convention.

London, England, Sept. 11.

H. C. H. SHENTON,
President, Institution of Sanitary Engineers.

Reference Books for Japanese Engineers

Sir—Referring to the letter published in *Engineering News-Record*, Sept. 6, 1923, p. 401, from Dr. J. A. L. Waddell, containing an appeal to American engineers for financial aid to Japanese engineers, there still exists an opportunity for us to give expression of our feeling of interest and sympathy for the engineers of Japan who have suffered so severely through earthquake, flood and fire. It is suggested that, in addition to any contributions which may be made for immediate and emergency relief, through established agencies, the engineers of this country might undertake to establish a memorial library or section of a library, which would be distinctly a contribution from the engineers of America to the engineers of Japan, this library to be made up of the latest editions of representative reference books on engineering subjects. It might also include, if procurable, bound volumes of leading technical journals. Most Japanese engineers read English and it is believed that such a library would be of substantial benefit.

If the above idea appears practicable, it is suggested that there probably is no American engineer having so wide an acquaintance with engineers of Japan, or an acquaintance extending over so long a period of years, as Dr. Waddell and that he might be prevailed upon to make inquiry as to the present status of engineering reference libraries in Japan with a view to securing data concerning specific losses and needs and also the most suitable and representative organization to which such a library might be dedicated. If it should develop, as is quite possible, that certain valuable reference libraries have been destroyed, an especially strong appeal could be made to the engineers of America.

New Orleans, Sept. 28, 1923.

ARTHUR M. SHAW,
Consulting Engineer.

More About Cat-Tails!

Sir—I read with a great deal of interest the article on p. 509 of the Sept. 27 issue in which you suggest that your Colorado correspondent may find it more profitable to cultivate rather than to eradicate his cat-tails.

If he is looking for suggestions I might say that within the last week I had a call from a man who has been experimenting with a light-weight concrete. When pressed for particulars as to the mix, he informed us that it was a 1:4:12, being respectively one part cement, four parts of sand and twelve parts of chopped up cat-tails. Further investigation disclosed the fact that the last figure was somewhat doubtful and the evidence was more that the mix was one part cement, four parts sand and $\frac{1}{2}$ acre of cat-tails.

If your correspondent can find a use for a concrete which has good nailing and insulating qualities according to our informant, and possesses a resistance to compression of somewhere between 50 and 75 lb. to the square inch (he did not say for how long) we won't make any charge if you want to pass this information (?) along to him.

New York City, Oct. 1, 1923.

W. F. LOCKHART,
Portland Cement Association.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

Completion of the Providence-Palmer branch of the Grand Trunk R. R. is reported to be under way. This is the 75-mile section of the Grand Trunk R.R. which was abandoned at the outbreak of the war. A considerable portion of the grading had been done at that time.

Flood Waters Rising in Gary, Ind. Sewers after each hard rain have caused an exhaustive survey to be instituted by City Engineer W. P. Cotttingham for data in connection with plans for the new municipal pumping station. The new plant will be situated on the Grand Calumet river where the storm sewers empty.

A Party of Officials of the Great Western Ry. of England, including G. Bulkey, docks engineer, has been visiting Canada to study methods of handling coal and grain at Canadian ports. It is also understood that one object of the visit is to interest Canadian concerns in the possibility of using Welsh coal.

Another Substantial Gain in the Net Earnings of the Canadian National Rys. is shown in the August operating reports. The gross earnings were approximately \$22,000,000 and the operating expenses \$20,000,000, leaving a net of slightly over \$2,000,000 as compared with similar earnings for August, 1922, of only a little over \$1,000,000. For the eight months ending in August, the net earnings were slightly over \$5,000,000 as compared with a deficit of over \$1,000,000 for the corresponding eight months in 1922.

Boston City Council Has Voted to accept the act for the extension of Dorchester Tunnel. The work is estimated to cost \$4,000,000 and to take from two to two and one-half years. Bids will be advertised within a few months and work will be started early next year. The new statute provides for the extension of the present Dorchester Tunnel from Andrew Square under Boston and Power Streets and Dorchester Avenue; for the construction of tracks in Harrison Square and thence for transportation over the Shawmut branch of the New Haven R.R. to Mattapan Station.

Secretary Hoover Has Appointed a committee consisting of Dr. George K. Burgess, chairman; Dr. F. C. Brown, H. D. Hubbard, and E. W. Libbey, to receive and disburse funds for the relief of dependents of those killed and injured by the explosion at the Bureau of Standards on Sept. 20, 1923. The committee at its first meeting designated Mr. Libbey as secretary and Mr. Hubbard as treasurer. It will be the duty of this committee to receive and disburse funds contributed for the relief of the injured and the families of those who were killed. Some contributions have already been received.

Missouri May Finish \$60,000,000 Road Program in 4 Years

The Missouri State Highway Commission has recommended to Governor Arthur M. Hyde that the contemplated time for the completion of the state's \$60,000,000 road program be reduced from 10 to 4 years, and that provision be made by the state for road maintenance funds. The commission estimates an average of \$200 a mile per year will be required to maintain the roads of the best type and from \$300 to \$800 a mile for the cheaper types. With sufficient maintenance the commission estimates the road program can be finished in 1927 with 90 per cent of the primary roads of the all-weather type. The Missouri Automobile Club recently went on record as in favor of an additional \$5 a year tax on automobiles, the money to be used for maintenance of roads. This would produce approximately \$2,000,000 annually.

First Concrete in Piers of Carquinez Strait Bridge

On Aug. 29 the first concrete was poured in the north anchor pier of the vehicular bridge to be erected across Carquinez Strait, one of the upper reaches of San Francisco Bay. Contract for the foundation work has been let by the American Toll Bridge Co., holders of the War Department permit, to Duncanson & Harrelson, contractors of San Francisco.

It is believed that this structure will be the third longest cantilever bridge thus far constructed and the longest one devoted exclusively to vehicular traffic. There will be two 1,100-ft. spans and two 500-ft. spans, the former consisting of two 300-ft. overhanging arms and a 500-ft. supported span. Previous reference to this bridge appeared in *Engineering News-Record*, Jan. 18, p. 135, and Mar. 22, p. 557.

New Sewage Disposal Plans for Madison, Wis.

With unexpectedly rapid increase in amount of sewage flow at Madison, Wis., the present sewage disposal plant (see *Engineering News-Record*, Sept. 11, 1919, p. 510) is already overloaded, the amount of pumpage estimated for 1930 having been reached in 1920. Plans for a new plant southwest of the city have been prepared by E. E. Parker, city engineer, and await approval by the State Department of Engineering. The effluent from the present plant is discharged into Lake Monona, but the new plans provide for discharging the effluent from both plants into the Yahara River which flows out of the lake. A bond issue of \$850,000 has been authorized, and bonds for about \$250,000 have been sold. Part of the land has been purchased. It is expected to do the excavation during the coming winter and to build the concrete work in the spring.

Many Millions to Be Spent by Southern Pacific

Starts Work on 118-Mile Line Over Cascade Mts.—New Double-Track Into Portland

The 1923 construction and improvement program of the Southern Pacific Company has as its main feature the completion of a new main line from Kirk to Oakridge, Ore. (Natron Cutoff), and line change to reduce grade and curvature from Black Butte to Grass Lake, Calif. Material is being assembled to lay five miles of track out of Oakridge, Ore. this year, on grade constructed in 1913; a contract has been let for 30 miles from Kirk, Ore., and work was started Sept. 1. The remaining mileage is being located.

Double-track work includes: building a new double-track entrance into Portland, Ore., double-tracking portions of transcontinental main line in the Sierra Nevada Mountains between Blue Canon and Truckee, Calif., portions of transcontinental main line in the Pequot Mountains between Wells and Montello, Nev., and portions of San Joaquin Valley main line in Tehachapi Mountains between Bakersfield and Mojave, Calif.

LINE CHANGES

Line changes include: changes in alignment at various points on the main lines between San Francisco and Los Angeles, to reduce running time, involving construction of a tunnel at Rocky Point, near Metz, Calif., and line revision at other points; line change near Mott, Calif., to get rid of a long, high trestle, and another line change together with the construction of second track, and a gauntlet-track bridge, at Yuma, Ariz.

Minor construction includes: branch lines in Imperial Valley, Calif., California easterly; and in San Joaquin Valley, Magunden westerly; the new freight terminal and automobile handling facilities at Los Angeles, and industrial trackage in San Francisco.

In the line of new structure the company will build new stations at Sacramento and Glendale, Calif., Reno, Nev., and Ogden, Utah; rock crushing plants at Santa Margarita, Calif., Palisade, Nev., and Lucin, Utah; a tie-treating plant for crossting ties, at Wilmington, Calif., an up-to-date planing mill at Sacramento, and machine shop at Los Angeles.

The program also includes installation of many miles of 110-lb. rail (the heaviest rail in use on the Pacific Coast) to replace 90-lb. steel; ballasting and reballasting of portions of the transcontinental main line Sparks, Nev., to Ogden, Utah, and Los Angeles to El Paso, Texas; construction of and improvement to station buildings at various points; construction of new sidings and extension of passing sidings; installation of automatic train-control devices and additional block signals; enlarging and concrete lining tunnels; construction of team tracks, etc.

Reciprocal Registration Operates in 12 States

Council of State Board of Examiners Reports Plan is Now an Established Fact

Reciprocal registration of engineers in twelve states that have laws regulating the practice of engineering is an established fact. Reports at the meeting in Chicago, Oct. 1 and 2, of the Council of State Board of Examiners indicated that Arizona, Florida, Oregon, Minnesota, North Carolina, South Carolina, Louisiana, Michigan, Iowa, West Virginia, Indiana and Colorado had ratified the articles of agreement on the subject adopted by the Council at last year's meeting. It is a plan to reflect in the examination for a reciprocal "card" a standard even higher than that required by any one of the states in the Council. The cards, which were printed by the Council and made available for the first time at the meeting, are the means of certification of the applicant's qualification from one state to another.

In the states accepting the agreement the card will be *prima facie* evidence of an engineer's qualification for a license in that state but it does not waive legal fees or such information other than evidence of qualification as required to conform to the rules of the examining board.

QUALIFICATION REQUIREMENTS

The principal qualification requirements (See *Engineering News-Record*, July 27, 1922, p. 156 and Oct. 12, 1922, p. 629) are as follows: Qualification shall be determined upon the basis of a detailed professional record on file in the state of which the applicant is already a registrant. Thorough consideration of this record shall constitute examination. Professional experience gained after eighteen years of age shall be considered as beginning only when the applicant shall have entered upon a position in professional engineering work requiring "original thought and responsibility." Examples of when experiences would begin to count are as follows: In the field, a position equivalent to that of a transitman; in the office, design not tracing; in teaching, a full time instructor in a recognized school. A progressive record of engineering experience for ten years, four of which is to be credited by graduation from a recognized school, is required.

Richard L. Humphrey, chairman of the State Board of Examiners in Pennsylvania, presented the situation in his state (not yet a member of the Council). The adverse minor court decision in the Stevenson case (see *Engineering News-Record*, Aug. 2, p. 180) has not halted the work of the board. About 2,500 engineers have registered and \$90,000 has been collected.

Reciprocal relations with Mexico and Canada are under consideration by the Council. A. B. Carter, Oregon, stated that his state has established reciprocal relations with British Columbia and Alberta.

The Council will meet next year the second Monday in November at Washington, D. C. The following officers were elected: President, Prof. G. M. Butler; vice president, G. F. Taylor; secretary, T. Keith Legare, Columbia, South Carolina.

One Dismissed as Result of Canal Bureau Investigation

The investigation into irregularities in the purchase of supplies in the canal bureau of the department of public works which was inaugurated by Governor Smith last week under the provisions of the Moreland law is to cover a period of nine years. Exorbitant prices, far in excess of current market quotations, charged the department by an Albany mill supply firm were adduced by the testimony taken last week, but so far no collusion has been shown.

J. W. Grady of Syracuse who was assistant superintendent of the department of public works has been dismissed from the service by Superintendent Frederick S. Greene.

New York Section of Am.Soc.C.E. To Open Fall Meetings

The first meeting of the New York Section of the American Society of Civil Engineers for the 1923-24 season is to be held Oct. 17 at the Engineering Societies Building in co-operation with architectural organizations of the city. The subject will be "The Relationship and Responsibility of the Architect and the Engineer in the Matter of Safety in Building Construction." Speakers include J. Vipond Davies, William Cullen Morris, R. C. Bastress, Robert D. Kohn and John Lowry, Jr.

Power Companies Merge

The Pennsylvania State Water & Power Resources Board has approved the application for incorporation from the Watts Water & Power Co. and the Juniata Water Power Co. These companies expect to build a dam at Iroquois on the Juniata River, which will form a reservoir of 1,500,000,000 gal.

Fred R. Low New President of A.S.M.E.

As a result of the recent election of the American Society of Mechanical Engineers, Fred R. Low, New York City, editor of *Power*, published by the McGraw-Hill Co., has been selected as president for the coming year. The vice-presidents elected are: H. Birchard Taylor, Philadelphia, Pa.; George I. Rockwood, Worcester, Mass.; and W. J. Sando, Milwaukee, Wis. William H. Wiley is the new treasurer. The nomination of Mr. Low for president was made in a convention in Montreal in the summer.

Fail to Get License to Develop Lock 17 on Warrior River

Acting upon the report of its engineers, the Federal Power Commission has concluded that it would not be justified in granting a license to the Alabama Power Co. for the development of power at Lock 17 on the Warrior River. The engineers report that the primary horsepower which could be developed on the Warrior River can be greatly increased by the construction of three storage reservoirs upon the upper reaches of the river and that the power site at Lock 17 is the key to the power situation in so far as the storage reservoirs are concerned; that no power company would undertake to build these reservoirs without first controlling the power site at Lock 17. The engineers also pointed out that the Alabama Power Co. has already undertaken two large projects on the Coosa and Tallapoosa Rivers and that it could hardly be expected to undertake the development at Lock 17 for some years. The Alabama Power Co. has been given until December 1 to file objections to the findings of the Commission's engineers.

Overloaded Truck Wrecks Canal Bridge

A FIVE-TON truck, piled high with radiators and boiler parts, completely wrecked the Hudson County bridge over the abandoned Morris Canal at Garrison Ave., Jersey City, N. J., about midnight, Oct. 2, 1923. The driver escaped without injury and no one else was on the bridge at the time. The bridge consisted of three 75-ft. Pratt pony trusses, pin connected, carried on cast-iron end posts resting on stone masonry abutments. The bridge was built in 1874 and shows no

indication of alterations other than the addition of a solid floor. Its capacity was plainly marked on large boards at each end as 8 tons, including truck and load. The steelwork appeared in good condition.

No doubt exists as to the cause of the failure, but the way in which it occurred is not yet clear. There is no indication of failure in any of the top chord members, and as the critical members of the lower chord are all in the mud, they cannot be examined until the debris is cleared away.

Moffat Tunnel Bids Present Unusual Details

Bidding on a six-mile mountain railway tunnel is so unusual that the following note as to the bids for the Moffat Tunnel in Colorado is of particular interest and is from information furnished by R. H. Keays, chief engineer for the Moffat Tunnel Commission.

Under the first call, bids on a unit price basis were to be received on Sept. 12, but no regular bids were received. There was, however, received from Ulen & Co., New York City, an irregular bid on a profit-sharing basis, naming a lump sum of \$6,075,000, which included \$486,000 profit. In fairness to other parties who might like to present similar propositions it was decided that this bid should not be considered. Immediately after its receipt other bids were received on a similar basis from many different contractors, none of which was considered.

It was then decided by the Board of Consulting Engineers to prepare a blank proposal for the use of the bidders which would put them all on approximately the same basis. This proposal named a preliminary lump sum bid of \$5,250,000, using the preliminary quantities as in the plans and specifications, the contractor to be required to name unit prices which, multiplied by the preliminary quantities, would amount to the above sum.

It was specified that if the work cost less than this sum the savings were to be shared equally with the contractor, in which case he would also get his fixed fee as stated below. Assuming that the actual cost of the work amounted to the above sum, the contractor was asked to state a fixed fee for which he was to do the work. If the work cost more than this sum, the contractor was to have 50 per cent of the extra cost deducted from his fixed fee, until his fee was reduced to a minimum fee, which he was also required to name.

A proposal on this basis was received from four bidders: Ulen & Co., New York City; Peter Seerie, Denver, Colo.; James McIlwaine, Denver, Colo., and Hitchcock & Tinkler, New York and San Francisco. These last bidders named a maximum and also a minimum fee of \$140,000 and their proposition was accepted. All extra work not mentioned in the unit quantities the contractor will perform on a percentage basis, being allowed 5 per cent on the cost of the work in question. In the final accounting, the amount of \$5,250,000, mentioned above, will be adjusted in proportion as the quantities may vary from the estimated amount.

Power Developments in Minnesota

The increasing demand for power in the neighborhood of Duluth, Minn., has stimulated great activity on the St. Louis River. Between Cloquet and Fond-du-Lac there is a total fall of 576 ft. The Northwestern Paper Co. is developing 40 ft. of this head at Cloquet and the Phoenix Utility Co., an operating company of the American General Electric Co., has already developed or is developing the remainder of the head except 53 ft. at Midway, and is now preparing plans to develop this last section. The present plans of the Phoenix Utilities Co. will involve an estimated expenditure of \$5,000,000.

H. M. Howe Memorial Service

A memorial service for the late Dr. Henry Marion Howe, president of the A. I. M. E. in 1893, will be held at 5 p.m., Oct. 25 in the Cathedral of St. John the Divine, New York City. This is the afternoon of the meeting in New York City of the American Iron and Steel Institute, which has established the Henry Marion Howe Lecture in tribute to Dr. Howe. The memorial meeting will be largely musical, but with short addresses, one of the speakers being Dr. Michael Pupin of Columbia University.

Ford Motor Company to Build Large Tunnel

Detroit Correspondence

The Ford Motor Co. expects to start construction in the immediate future on a new condensing water tunnel at its River Rouge plant. This new tunnel will be approximately 25 ft. in diameter and 12,000 ft. long. The present 12 ft. 8 in. tunnel was driven through very soft material by the shield method, using concrete blocks for the lining and back-filling around the outside with packed gravel. As the new tunnel is to be driven through similar material it is expected that the new tunnel will be driven by the same method that was used in driving the former tunnel.

Steel Erection Derrick Falls

Failure of a guy cable caused the fall of one of four large guyed derricks employed in the erection of the steel frame of the headhouse for the Chicago Union Station, on Sept. 19. By good fortune nobody was hurt and very little damage was done to the steel framing. Both the mast and boom crumpled up where they fell across the floor girders, as shown in the accompanying view, while the head of the mast, with its mushroom plate for the attachment of the guys, was bent back at a sharp angle when it struck the street. These steel derricks are of box lattice construction with 125-ft. masts and 115-ft. booms and can handle 40-ton loads. Each mast is stayed by eight 1½-in. wire cables, but under the conditions of

FALLEN DERRICK AT CHICAGO UNION STATION

erection the guys are not of equal length. It is stated that in hoisting a relatively light load with the derrick in question the load on the guys was not equally distributed but became concentrated on one of the short guys, which broke under the strain.

Bureau of Standards Explosion Caused by Gasoline Leak

Explanation of the cause of the explosion in the dynamometer laboratory of the Bureau of Standards Sept. 20, 1923, resulting in the death of four employees and the injury of six, is given as follows by the board of inquiry which investigated the accident at the request of Herbert Hoover, Secretary of Commerce.

"The explosion was caused by the ignition of a mixture of gasoline vapor and air in the altitude chamber. The research under way was concerned with comparative tests of fuels of differing volatility, and aviation gasoline was under test at the time. The board believes that the presence of the gasoline vapor in the chamber was due either to a leak in the feed line leading to the carburetor of the engine or to a leak from the carburetor due to the sticking of the float mechanism. This conclusion is supported by a remark made by one of the members of the testing staff an instant before the explosion, to the effect that the gasoline readings which he was taking indicated the presence of a leak.

"The condition of the set-up following the fire is such that it is not possible to establish which one of the above causes occasioned the leak. Since it is known that only three gallons of gasoline had been drawn for the test, that the engine had been running from about 11 to 12 o'clock with the chamber open, that the chamber was closed at about 12:30 for the purpose of running at a lower temperature, and that the engine had been operated from about one to two o'clock with the chamber closed, it is believed that not more than a quart of gasoline could have escaped into the chamber. This amount, however, if evaporated would have been sufficient to account for the energy of the explosion.

"The probable source of the ignition was a back-fire through the carburetor. Support to this conclusion is given by the statement of one of the survivors that he heard the engine backfire immediately before the explosion.

"The explosion threw out of the chamber a closed apparatus containing about 10 gal. of heavy lubricating oil and about 5 gal. of toluol, breaking the pipe connections and thus releasing part of the contents which furnished additional fuel for the fire which followed. The explosion also shattered the fuel-measuring system used in the test, which was outside the chamber and contained about two quarts of gasoline. This was the only gasoline supply involved in the fire.

"Special mention should be made," continues the statement, "of the action of C. M. Smith, engineer in charge of the ammonia plant, who after being blown out of the building and badly cut about the head, returned to the wrecked chamber and shut off two ammonia valves, and then went to the refrigerating plant in the basement and operated it to pump the ammonia out of the coils in the wrecked chamber. This action may have prevented further loss of life and the destruction of the entire building by fire."

L. J. BRIGGS
Chairman.

Board of Inquiry—L. J. Briggs, F. C. Brown, E. F. Mueller, W. S. James, and H. D. Hubbard.

Random Lines

Odds Are Agin 'Em

It is almost hopeless, says the *Minneapolis Journal*, for the autoists to try to destroy all the locomotives at the railroad crossings. The Baldwin works alone are turning out a locomotive every hour.

* * *

From a sob story in the *Chicago Tribune*:

"And the grief stricken mother went over again the story how she shot her 19-year-old son 'To save his soul.' He wouldn't work, loafed all the time, because he could not get a job at his profession as a Civil Engineer after graduating from the Crane Technical High School. He would not do anything else and chose the easy way of stealing."

* * *

A Magnificent Gesture

In New Orleans they have either achieved the desirable end of humbling the automobile driver or they are breeding an especially virile crop of pedestrians. The accompanying sketch is from the new traffic rules just issued in the Crescent City. After some stirring escapes at Sixth and Broadway in Los Angeles, Michigan Ave. and Madison in Chicago, Market St. near the Palace Hotel in San Francisco, the Campus

Martius at Detroit, and Fifteenth and New York Ave. in Washington—not to mention at all the god-like disdain the New York City motorist displays toward the pedestrian—we wonder at the calm bearing of the southern gentleman crossing Carondelet St. As a gesture it is magnificent, but we trust he has his family well protected with insurance. Probably the driver is not shown in the picture because the language that he is emitting has distorted his countenance beyond fair presentation.

* * *

The Inspired Composer

According to the Associated General Contractors news letter a well known drill maker has announced a policy of price reduction commiserate with the reduction in manufacturing and material costs.

* * *

"Sale of Naval Vessels for Scrapping Purposes" is the title of a catalogue just issued by the Navy Department. We thought that was just what the Washington Conference was aimed to prevent.

Lee H. Landis Is Made General Manager of Alaska R.R.

The Secretary of the Interior has announced the appointment of Lee H. Landis, of San Francisco, as general manager of the Government railroad in Alaska, effective Oct. 1. The appointment of Mr. Landis is the result of an announced decision on the part of the Secretary of the Interior, now that actual construction of this railroad is practically completed, to place an experienced railroad man in charge of its operation.

Mr. Landis' experience in the transportation business began over thirty years ago as an agent and train dispatcher on the Philadelphia & Reading R. R. Since that time he has been a general agent in the operating and traffic departments of the Santa Fe and the Southern Pacific, general manager of the Phoenix & Buckeye R. R., general manager of the Ocean Shore R. R., assistant to the president of the Tidewater Southern R. R., president and general manager of the San Jose Terminal R. R. of California, and general manager of the Fresno Interurban Ry. During the war, Mr. Landis was a major of engineers in the Engineering Corps in Europe for two years, during which time he served in various capacities in the transportation department of the A. E. F. He is now a lieutenant colonel in the Engineer Reserve.

Since the close of the war Mr. Landis has served as industrial commissioner of the Western Pacific Railroad System, with headquarters at San Francisco.

New Zealand Starts Development of Its Vast Power Resources

Estimates of the amount of available water power in New Zealand, forwarded to the Department of Commerce by Vice Consul J. C. Hudson, show a total of 4,076,700 hp., of which 759,700 hp. is in the North and 3,317,000 in the South Island. In the distribution of power resources, the South Island is in an advantageous position as the bulk of its potential supply is located near the deep water sounds of the west coast, where there are many sites suitable for electro-chemical and electro-metallurgical industries.

A program for water power development has been laid out in which the important sites of the North Island will be utilized. These include Lake Waikaremoana, which has sufficient storage capacity to run the proposed generating plant for 21 months without rainfall, and the Waikato River project which tops Lake Taupo. The first installment will involve an estimated expenditure of \$15,000,000 for the headworks, plant and transmission line to Auckland, and will develop 50,000 of the 138,000 hp., which it is estimated can be ultimately obtained.

State commitments up to the end of 1923 for the Lake Waikaremoana project amount to \$110,000. By the end of 1924 it is planned to spend \$1,075,000 when it is expected that 24,000 hp. will be available from this source. The method of financing hydro-electric development in New Zealand is chiefly through State aid, no projects of importance being promoted by private organization. Southland province with some assistance from the State is carrying on its development through the Southland Power Board.

A.G.C. Committee Studying Bidders' Responsibility

In order to define responsibility as applied to construction companies and to devise practical means of selecting responsible bidders for a given project, the committee on ethics of the Associated General Contractors has begun an intensive study. By this procedure the association hopes to remove the disagreeable controversies that frequently result when engineers disqualify contractors as irresponsible bidders. According to an announcement made by the A. G. C., in the co-operative work which the association has been doing with the joint conference on contracts and the American Association of State Highway Officials, the inter-departmental board of contract and adjustment and various local agencies, practically each issue discussed has been connected with the question of a bidder's responsibility. The opinion has often been heard that engineers and public officials would be glad to adopt certain contract principles if they possessed the means for awarding contracts to responsible companies only.

The committee on ethics in undertaking this work is desirous that construction companies throughout the country give it their careful thought and forward to the Washington office of the A. G. C. any suggestions. The committee defines the elements of responsibility as follows: (1) Financial strength, which includes not only a financial statement to indicate the condition of the bidder's business, but a statement of funds available for the project and banking references; (2) personal experience of construction manager, proprietor, partner or company official in charge of construction; (3) construction plant available for the project; (4) construction performance record; and (5) personal references for successful construction service.

The committee suggests that certain qualifications be put upon bidders before they are allowed to submit proposals, instead of after bids are received, so that the principal ground upon which a disqualified bidder can secure taxpayers' injunction, namely, the award of a contract at a higher price, is removed. Various other reasons for qualifying bidders include a saving of the expense in field investigation and estimating on the part of any who cannot qualify for a particular project.

101 Contractors Bid for 11 Road Jobs in North Carolina

The North Carolina State Highway Commission awarded contracts recently for eleven projects. There were 101 bidders for the work. The total mileage let was 72.99 miles, costing, exclusive of the usual 10 per cent for engineering and contingencies, \$1,885,718. Of this there were 56.95 miles of standard concrete paving, which cost \$30,340 per mile including grading, draining, bridges, culverts and all other items of construction.

The remaining 16.04 miles let consisted of earth or topsoil roads and cost \$7,424 per mile including all items of construction mentioned above.

The reinforced concrete bridges and culverts, included in the above figures, amounted to \$178,871, or about \$2,450 per mile of road constructed.

Civil Service Examinations NEW YORK STATE

For the following Civil Service examinations apply to the New York State Civil Service Commission, Albany, N. Y. The positions are open to applicants not residing in the state of New York. Both examinations are to be given on Nov. 3.

Assistant Sanitary Engineer—New York State Department of Health, salary \$3,000 to \$3,500. The duties of the position require a knowledge of the design, construction, operation and supervision of water supply systems, water purification works, sewerage and sewage disposal systems and prevention of stream pollution; also four years' experience in such work.

Assistant Sanitary Engineer—New York State Department of Health, salary \$2,100 to \$2,500. The duties of the position include investigations and reports on construction and operation of water supply and sewerage systems and water and sewerage treatment works, community sanitary conditions.

Engineering Societies

Calendar

Annual Meetings

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 17-20.

AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga., Nov. 12-16.

CITY MANAGERS ASSOCIATION, Lawrence, Kansas; Annual Meeting, Washington, D. C., Nov. 13-15.

AMERICAN ROADBUILDERS' ASSOCIATION, New York City; Annual Convention, Chicago, Jan. 14-18.

The Engineering Institute of Canada, Montreal Branch, resumed on Oct. 4 its weekly meetings, this week's topic being "The St. Lawrence Deep Waterways" presented by E. A. Forward, consulting engineer, Montreal.

The Society of Terminal Engineers held its regular meeting, with a dinner, in New York City Oct. 9 and on the subject, "Co-Ordination of Railroad and Marine Terminals," Col. Edward Burr, formerly U. S. district engineer officer, first New York district, was the speaker, the discussion being taken up by Francis Lee Stuart, J. J. Mantell, vice-president of the Erie R.R., Col. Charles Hine, and E. H. Lee, vice-president of the Chicago & Western Indiana R.R.

The Engineers Club of Philadelphia and the Philadelphia Section of the American Society of Civil Engineers will hold a joint session during the afternoon and evening of Oct. 16 at which the pollution of streams with special reference to industrial wastes will be discussed. The speakers will be Dr. W. H. Frost, surgeon of the U. S. Public Health Service, George W. Fuller, C. A. Emerson, Jr., Col. F. C. Boggs, Almon L. Fales, W. L. Stevenson, Maj. J. A. Vogleson, and J. W. Ledoux.

The Boston Society of Civil Engineers at its monthly meeting Oct. 19 will have as speakers giving "Brief TalksonEngineeringandConstruction," W. F. Williams, commissioner of public works for Massachusetts; J. W. Rollins, of Holbrook, Cabot & Rollins, contractors for masonry and concrete construction; W. H. Sayward, secretary of the Master Builders Association; J. Parker Snow, consulting engineer; C. T. Main, industrial engineer; and C. R. Gow, engineer and contractor for foundations.

Personal Notes

ERNEST R. ROBINSON, now water supply engineer for the Solvay Process Co., chemical manufacturers, Syracuse, N. Y., was formerly engaged in civil engineering work for the Hudson River Bridge Co., of New York City.

H. E. TEWELES, who had been structural designer for the United States Gypsum Co., Chicago, Ill., is now connected with Albert Kahn, architect and engineer, Detroit, Mich., in the same kind of work.

JOHN R. NICHOLS, formerly chief engineer of Monks & Johnson, Boston, Mass., has opened a consulting engineering office at 161 Devonshire Street, Boston, for practice in the design and construction of industrial plants and general structural and construction engineering.

H. B. MILLER, assistant city engineer, Chicago, has been dismissed from office by Col. A. A. Sprague, commissioner of public works. Mr. Miller held his position on temporary appointment by the former administration. Major Myron B. Reynolds, engineer of water-works design, is acting assistant city engineer, pending a permanent appointment.

EXUM M. HAAS, Cleveland, Ohio, who until recently was manager of the railroad department of the H. K. Ferguson Co., announces that he is open for engagement as consulting engineer in locating, laying out and designing railroad shops and terminals, and gap crane and other types of locomotive erecting.

FRANCESCO MAURO, engineer and architect, has terminated his connection with Martin J. Lide, and has opened an office for the practice of structural engineering and architecture in the First National Bank Bldg., Birmingham, Ala.

PRESTON L. FITE, formerly with the North Carolina State Highway Commission, Greensboro, N. C., and the California State Highway Commission, Sacramento, Calif., has returned to work with the North Carolina commission as resident engineer at Reidsville, N. C., on an 8-mile concrete road project.

MAURICE DEUTSCH, architect and engineer, announces the removal of his offices from 50 Church St., New York City, to the 12-story building which he recently purchased at 35-39 Maiden Lane, New York City, and to which he is adding another floor.

ORLEY GREY, Wabash, Ind., superintendent of the Fort Wayne highway district has resigned to enter the contracting business.

S. J. NORRIS, civil engineer, Oroville, Calif., has been appointed chief engineer of the Honcut-Yuba Irrigation District in Yuba County, Calif.

RUSSELL M. DUFF, Canton, Ohio, has resigned his position as superintendent of state highways in Columbiana County and will take up post-graduate work at Cornell University.

OLIVER ANTRUM HALL, formerly designing engineer, Alaska Road Commission, with headquarters at Juneau and Anchorage, Alaska, has severed his connection with the commission and opened up an office in the Seaboard Building, Seattle, Wash., as engineer on bridges and buildings.

Obituary

MAJOR DANIEL D. PULLEN, Corps of Engineers, U.S.A., died Sept. 24 in a hospital in Washington, D. C., after an illness of two months. He was 38 years of age. Major Pullen was a native of Washington state and a West Point graduate of 1910. He served with the Engineers in France, rising from lieutenant to major, and won the Distinguished Service Cross, the Croix de Guerre and two citations.

WILLIAM P. JONES, resident engineer during the building of the Georgetown loop on the Colorado & Southern R.R., engineer for public works at Denver, Colo., from 1889 to 1901, died suddenly, Sept. 24, at the home of his sister in Louisville, Ky.

F. W. COOK, vice-president of the San Antonio Portland Cement Co., died Sept. 3 in a hospital in Chicago after a two months' illness. Mr. Cook was born in Kentucky and was educated in the University of Indiana and the University of Heidelberg, Germany. He was connected with the San Antonio Drug Co. from 1895 to 1908 and in the latter year organized the San Antonio Portland Cement Co., which is the successor to the older Alamo Cement Co., organized in 1880.

A. H. ANDERSON, professor of engineering at the University of Wisconsin, died at his home in Madison, Wis., Sept. 1. Prof. Anderson was for several years professor of steam and gas in the department of engineering at the University of Wisconsin.

FORRES MCGRAW, secretary-treasurer of Swanson-McGraw, consulting engineers, New Orleans, La., was electrocuted in an accident at the Plaquemine, La., water-works Sept. 19 and death was instantaneous. Mr. McGraw was 27 years old, and the son of John McGraw, general agent at New Orleans of the Southern Pacific Ry. After graduation from Tulane University, he entered the employ of Fairbanks-Morse Co. and later with Mr. Swanson, an employee of that company, established the firm of Swanson-McGraw, consulting engineers. During the War he served as an instructor at Camp Beauregard and at Fort Sill.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Notes on Care of Wire Rope

From a paper by William Constable, mechanical and electrical engineer, Republic Iron & Steel Co., presented Aug. 30 at the annual meeting of the Lake Superior Mining Institute.

Rope used for hoisting and haulage usually ranges in diameter from 1 to 2½ in.

Grooved hoisting drums are preferable to flat-faced drums; pitch of grooves should be ½ in. larger than rope diameter; diameter of drum should be not less than 60 times diameter of rope.

Diameter of head sheave for shaft hoist should be 80 times diameter of rope. The following groove diameters on sheaves are recommended: For rope ¾ to 1 in. diameter, ⅝ in. larger groove diameter; for rope 1 ⅛ to 2½ in. diameter, ¾ in. larger groove diameter; for rope 2½ in. and upward, ⅞ in. larger groove diameter.

Attachment of rope to cage or skip should be by means of a wire rope socket with zinc attachment to develop full strength of rope.

Abrasion of rope on inclined haulage work should be avoided by the installation of rollers not less than 6 times the rope diameter and spaced 25 to 30 ft. apart.

When cutting steel wire rope it is essential to place three sets of seizings on each side of the cut to prevent disturbing the uniformity of the rope. Annealed iron wire should be used for seizing purposes.

A wire rope received in a coil should be unrolled on the ground like a hoop and straightened out before attempting to pass it around sheaves.

Wherever a spliced eye, clip or clamp connection is used, it is necessary to employ a wire rope thimble around which the rope is passed to protect it from being mashed or distorted when strain is applied.

Reverse bends should be avoided in wire rope installation.

Lubrication of wire rope is highly important. A lubricant applied hot will generally give good service because in its heated condition it will penetrate and then, upon cooling, will congeal into a plastic filler throughout the rope.

Japan Admits Building Materials Free Until March 31

Building materials and the necessities of life have been exempted from import duty until March 31, 1924, by virtue of an imperial ordinance promulgated in Japan according to advices received from the Consulate General of Japan, New York City, and forwarded to the Department of Commerce. Under the same imperial ordinance, the import duty on automobiles, other than motor trucks, but including automobile parts and motive machinery, has been reduced by one-half for the same period. Information concerning specific commodities affected by this decree will be furnished upon request by the Department of Commerce, Washington.

New Financing for Lakewood Company

New financing by the Lakewood Engineering Co., Cleveland, Ohio, involves the issue of \$400,000 first mortgage, ten-year, 7 per cent sinking fund gold bonds, which are being offered for public purchase at par and accrued interest to yield 7 per cent. The bonds are in denominations of \$1,000, \$500, and \$100, interest being payable semi-annually.

The company, which was founded in 1896, manufactures concrete mixing and handling machinery and trucks and trailers for factory and warehouse haulage. During the year 1922 the company made a profit applicable to interest of \$143,609 and for the first six months of the current year earnings have totaled \$86,957.

Builders Shun Proper Equipment, Says Manufacturer

A letter to the Editor

Sir—You may be interested to know that the editorial "Building Methods Primitive," on p. 498 of the Sept. 27 issue of *Engineering News-Record* crystallized some thoughts of the writer. On the majority of small building operations you will see time lost and costly errors made because a level-board and string are being used instead of a surveying instrument such as the convertible level or transit. In addition to our own make there are several comparatively low-priced yet reliable instruments on the market at convenient terms to aid the small builder in establishing accurate lines and levels quickly.

In the writer's opinion the cause for the general backwardness in the development of machines for individually small operations is the atmosphere of "doing" in which the builder lives as compared to an atmosphere of "planning." He can be criticized more fairly for being too "practical" than he is justified in claiming the engineer to be too "theoretical."

The Warren-Knight sales efforts of necessity have been stronger in selling builders the idea of utilizing a convenient and reliable convertible level or a builders' transit than on the effort to sell our particular trade name. Builders will find manufacturers ready to give the effort for developing time-saving machines for individually small operations if they would show more interest in them. Since the builder is so engrossed in rushing around on a job in actual operation or in hunting for more contracts, perhaps it would pay him to increase his overhead to the extent of securing the services of an engineer who could reduce operating costs by utilizing such equipment as is now available.

This condition covered by your editorial is widespread and worthy of attention.

J. O. PRESTON,
Warren-Knight Co.

Philadelphia, Oct. 1.

Construction Equipment at Mining Congress

Exhibit Includes Variety of Heavy Machinery—Equipment Problems Discussed in Open Forum

Engineering News-Record Staff Report

FOR the contractor or the manufacturer of construction equipment the two features of special interest at the American Mining Congress, held in Milwaukee Sept. 24-29 were an exhibit of machinery and appliances and an open forum or series of discussions on subjects relating to mining equipment and methods.

Exhibits—An extensive display of machinery and equipment used in mining and also in metallurgical work filled the floor of the main hall in the Municipal Auditorium. Many of the machines were in operation and one enterprising exhibitor of a mucking or coal-loading machine had dumped a few tons of coal into his exhibit space, the machine continually digging this up from one spot and depositing it in another. On a vacant lot outside the hall another machine of the same type was handling a rock pile.

The number of visitors was rather small, since many of the men attending the Congress were interested in legislative, social and economic matters rather than in actual mining operations. Much of the equipment exhibited is or might be employed on construction work. Without attempting to enumerate all the exhibits the following list indicates appliances of use for general construction purposes rather than for mining exclusively.

RANGE OF EXHIBITS

1. Excavating machinery—Bucyrus and Pawling & Harnischfeger.
 2. Mucking machines for mine or tunnel work—Hoar, Jeffrey, Joy, Myers-Whaley, Shoveloder and Thew. The last named company showed the new machine designed by engineers of the St. Joseph zinc mines and described in *Engineering News-Record* of May 31, p. 981.
 3. Portable conveyors for loading cars and handling materials—Manierre and Ottumwa.
 4. Industrial locomotives, steam—Baldwin, Heisler and Lima; electric—General, Goodman, Ironton, Jeffrey, Mancha and Westinghouse; gasoline—Milwaukee.
 5. Mine and dump cars—Lorain and Western.
 6. Mine and industrial track, ties and switches—Bethlehem and Lorain.
 7. Drills—Sanderson-Cyclone and Diamond.
 8. Pumps—Layne & Bowler, Midwest, Prescott, and Worthington.
 9. Wire Rope—Broderick & Bascom, MacWhyte and Williamsport.
 10. Explosives—Atlas, Hercules and DuPont.
 11. Screening Plants—Allis-Chalmers, Roberts & Schaefer, Robins Belt and Smith Engineering.
 12. Chain drives—Chain-Belt and Morse.
- Exhibits of a special character were those of the U. S. Bureau of Mines, including mine rescue work and safety appliances, and the Colorado School of Mines. The Milwaukee Public Library exhibited shelves of its books on mining and mining machinery; an attendant was in charge to give information. The

Milwaukee Public Museum also had a case of ore specimens as an example of the exhibits to be found in the museum.

Open Forum.—A series of discussions on mine equipment problems was based on practical questions submitted by both manufacturers and mining men so as to bring out the viewpoints of the makers of equipment and the men who use it. A discussion on rock drills related largely to the value of air-drills and churn or well-drills for open workings, but it was stated that no churn-drill now available has sufficiently low head room for use in mines. Economic use of explosives in coal mining was actively discussed by mine operators, miners, state mining officials and makers of explosives. It was generally agreed that there is need for a campaign of education as to the use of explosives. A reduction in the present excessive amount of explosive per ton of coal produced would result in a greater proportion of coal in the larger and more valuable sizes, while there would also be greater safety in mining. It was voted to appoint a committee to consider such a campaign.

The program of discussions was not followed strictly, but among the subjects listed were the following, some of which have a relation to engineering construction work: Shoveling and loading machines for underground work; the caterpillar mount for shovels; mine transportation; crushing and screening; hoisting plant; pumps and mine drainage; underground power equipment and transmission; drilling machines and drill steel; wire rope; use of traveling cranes at mills and smelter plants; applications of welding in mining work; track equipment and standardization of gage for mine tracks; gasoline, electric trolley and storage battery industrial locomotives; safe equipment for hoists, pumps and loading machines in gaseous mines.

Business Notes

WALSH & MCGEE STEEL CO., New York, announces that its new rolling mill constructed on tidewater at Newark, N. J., has begun operation. The mill is designed especially for rolling light steel sections such as 4 and 8-in. round, plain and deformed bars, small angles, channels, flats, tees and other sections.

LINK-BELT CO., Chicago, according to an announcement just made by its president, Charles Piez, has purchased the Meese & Gottfried Co., San Francisco, Los Angeles, Seattle and Portland, to improve its distributing facilities on the Pacific Coast which had previously been handled by subsidiary organizations under the names of the Link-Belt Northwest Co., of Seattle, and the Link-Belt Pacific Co., of San Francisco. Meese & Gottfried Co. and its predecessors, have been manufacturers of power transmission machinery and distributors of conveying and transmission machinery on the Coast for more than forty years. It is the intention of the new owners to add to the facilities and enlarge present stocks, so that prompter service to its customers will be insured. The new organization will be known as Link-Belt Meese & Gottfried Co., with head-

quarters at San Francisco. The officials will be: Charles Piez, chairman of the board; B. A. Gayman, president; Harold H. Clark, vice-president and sales manager; Leslie W. Shirley, treasurer; and Richard W. Yerkes, secretary.

Equipment and Materials

Highway Lighting Unit Throws Long Beam Parallel to Road

Through a combination of parabolic reflectors and refractor prisms a highway lighting unit, developed by the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., effects a marked economy in the distribution of its illumination by casting its rays along the road in a long, narrow path. Another feature of the unit is the elimination of glare which is not only objectionable to the driver of a vehicle, but has been responsible for many road accidents.

As shown in the accompanying sketches, the lighting unit consists of a porcelain housing containing a Type C lamp, a silver-plated parabolic reflector, and a double set of refracting prisms. The unit is arranged for suspension from a series of interchangeable fittings to be fastened to brackets, mast arms or span wires, as mounting

conditions require. The unit is generally placed at least 25 ft. above the road surface.

The parabolic reflector is so arranged with relation to the refractor prisms that all of the light is distributed without waste in a direction parallel to the roadway. The glare elimination feature is accomplished by positioning the edge of the reflector so that the light in a line parallel to the direction of travel is cut off at a direct angle of 14 deg. below the horizontal—the angle which has been determined by exhaustive tests to be the most practical. The complete highway lighting unit weighs 100 lb.

New Balanced Three-Way Valve for 21-E Paving Mixer

A new three-way balanced valve, designed to prevent leakage by the elimination of metal-to-metal seats common on former types, has been perfected by the Koehring Co., Milwaukee, and is now installed as standard equipment on its 21-E pavers. All of the valve parts which come in contact with water are made of either bronze, brass, rubber or leather, preventing corrosion. The valve, which is equipped with rubber discs and leather plunger (standard

Jenkins parts), is balanced, automatically operated, non-freezing, self-draining and accessible.

Inspection of the valve can be made easily by removing three bolts and one pin connection, allowing the entire unit to be pulled out of the valve body, as shown in the accompanying illustration. The valve can be dropped back into place without any fitting or adjusting. To turn the three bolts down and make the pin connection to the operating levers, is only a few minutes' work. A removable house protects the valve and outside valve parts from stone, sand

and cement which may drop from the charging skip.

An additional time-saving feature is the automatic opening of the valve to discharge water into the drum by means of an arm which opens the valve when the skip is raised. The time of opening the valve is adjustable in the valve-operating mechanism. A hand control is also provided for operating the valve.

Rubber-Tired Wheels for Construction Equipment

A development in its agricultural type of wheel is announced by the Geneva Metal Wheel Co., Geneva, Ohio, in the form of rubber-tired wheels for construction equipment. With such wheels equipment may be hauled from one job to another by motor trucks at higher speeds than is possible with metal rimmed wheels and also with less damage to the equipment from vibration and impact. The new type of wheel, shown in the accompanying illustration of a mechanical loader handling road material in Ashtabula County, Ohio, has hubs equipped with a

special type of roller bearing. The production of rubber-tired wheels is a new field for the Geneva company and its plant is now being equipped to manufacture this equipment for all standard rubber tire sizes.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Brick and Cement Importations Increasing

Foreign Brick Receipts During Second Quarter 1200 Per Cent Above 1922—Slight Gain in Cement

Although importations of foreign building materials has never yet been an important factor in the construction situation, the present high price level has given rise to considerable discussion of the subject. Importations of brick and cement are light as compared with domestic production and consumption, but it is worth noting that they appear

been absorbed. This competition is not likely to reach far inland, but would affect Atlantic ports unless the American manufacturers in those locations find some protection."

The amount of foreign shipments to New York in the second quarter of 1922 and 1923, furnished by the Bureau of Foreign and Domestic Commerce, is as follows:

	1922	1923	Invoice Value
	Thousands	Thousands	Value
April, Mercet	220	5,494	\$31,916
May	217	2,706	22,741
June	312	1,979	17,009
	749	10,379	\$71,666

The Bureau of Foreign and Domestic Commerce, of the Department of Commerce, reports that the imports of hydraulic cement in June, 1923, amounted to 11,559 bbl. The total imports in 1922 amounted to 323,823 bbl.

The exports of hydraulic cement in

June, 1923, were 77,203 bbl. valued at \$236,166.

The effect of competition always shows in the prices. That foreign entry into American brick and cement markets has not reduced prices is proved by the charts for New York.

Recent Unit Bids Throughout the Country

Although it is impossible for *Engineering News-Record* to quote formal prices at hundreds of centers throughout the United States, a workable acquaintance with construction cost in outlying districts may be had by studying the unit bids published in *Construction News*. For the reader's convenience representative bid prices on various materials and operations applying on a number of the more important contracts awarded during the last two months are presented in the table.

UNIT-BID PRICES ON IMPORTANT MATERIALS AND OPERATIONS IN RECENT CONTRACTS AWARDED

Where Located	E.N.-R. Issue	Nature and Extent of Job	Unit Bid Price
Arkansas	Sept. 6	22 mi. single track railway	\$125,000
Calif., Merced	Sept. 20	6,000 cu. yd. dredging, per cu. yd.	3.79
Calif., Los Angeles	Aug. 30	100,000 cu. yd. dredging, per cu. yd.	2.44

Oregon	Sept. 13	38,000 cu. yd. common excav., per cu. yd.	1.32
		3,000 cu. yd. solid rock excav., per cu. yd.	1.50
Tenn., Memphis	Aug. 23	15,000 bbl. cement (o.b. Memphis siding, per bbl.	3.11
Tex., Ennis	Aug. 23	14,500 ft. 10-in. class B, c. pipe, per ft.	2.60
Tex., Abilene	Aug. 9	40,000 sq. yd. 2-in. bitulithic pavement, per sq. yd.	2.32
Utah, Salt Lake City	Sept. 6	2,174 cu. yd. common excav., per cu. yd.	.50
		1,500 cu. yd. borrow, per cu. yd.	.50
		9,625 cu. yd. common excav., per cu. yd.	.50
		4,375 cu. yd. borrow excav., per cu. yd.	.50
		62,000 cu. yd. earth excav., per cu. yd.	.50
Washington	Sept. 6	45,730 cu. yd. common excav., per cu. yd.	.50
		3,300 cu. yd. loose rock excav., per cu. yd.	.80

to be increasing. In April, May and June of this year 10,379,000 common brick came in through the port of New York, against only 749,000 in the same quarter of 1922. Cement imports through New York were heavier by 41,858 tons in this same quarter of 1923 than one year ago. In addition, 9,687 tons of white, non-staining cement were imported against none last year. That American brick men are appreciative of the situation is evidenced by

the following statement by the Common Brick Manufacturers' Association of America:

"For the first time during the business career of anyone now manufacturing brick some competition is felt from foreign made brick. This is apparent so far only in the New York market, where considerable quantities of brick from Germany and Holland are reported to be coming in. It is stated that these brick can be purchased on board ship at German and Holland prices for \$4 a thousand. It is apparent at once that American manufacturers cannot compete with this low production cost even after transportation and handling on this side of the ocean has

Production and Materials Stocks In Eleven Cities

Substantial Reserves of Brick and Lumber—Cement Output Highest on Record—Drop in Steel and Iron Output

Iron and Steel—Production has fallen off somewhat in both iron and steel during the last month. The average daily pig-iron output during September was approximately 99,811 tons, against 110,816 in August and 124,764 in May, which was the highest month in the history of the industry. The September steel ingot output totaled 3,159,283 tons against 3,506,755 during August and 4,000,695 in May, which was the peak month of the year, according to the American Iron and Steel Institute. While there has been a marked decrease in production and demand, consumption has been kept up in that buyers have been drawing heavily upon their reserve stocks.

Lumber—The present output is about 5 per cent above normal as against 7 per cent above, one month ago and 3 per cent below normal one year ago. Shipments are 105 per cent and orders 115 per cent of normal production, according to the National Lumber Manufacturers' Association. While production fell off slightly, shipments and orders gained during September. One year ago production was 97 per cent of normal with shipments 90 and orders 85 per cent of normal production. The following table shows lumber movements during the four weeks ending Sept. 29, compared with the preceding four weeks:

	Four Weeks Ending— Sept. 29, P.T. B.M.	Sept. 1, P.T. B.M.
Cut	1,078,921,770	1,082,683,351
Shipments	963,864,271	925,944,072
Orders	1,022,562,432	887,295,317

Cement—The August cement output was the heaviest on record, with 12,967,-

000 bbl. against 12,620,000 for the month preceding. August, 1922, however, totaled 11,664,000 bbl. Reserve stocks throughout the entire country Sept. 1 totaled 6,077,000 bbl. as against 5,716,000 for the corresponding period in 1922, according to the Geological Survey. Compared with this time last year, the cement situation is one of increased production, shipments and stocks on hand.

Brick—Report of the Common Brick Manufacturers' Association of America as of Sept. 1 shows 250,176,000 burned brick on hand at yards throughout the country, compared with 179,574,000 on Aug. 1. There has been a slight decrease in orders on books with a corresponding increase in stocks on hand, since there has been no slackening of production. Northern brickyards are storing brick in anticipation of a heavy 1924 demand. Many of the plants in the agricultural states are closed on account of insufficient demand for brick.

San Francisco—Warehouses fairly well stocked with lime, track supplies and blue annealed steel sheets; large supplies of steel structurals, bars, triangle mesh, metal lath and common brick. Large natural reserves of road oils and asphalt. Plenty of hollow tile, sewer pipe, drain tile, cement and galvanized sheets.

Los Angeles—Supply of building materials keeping pace with demand, with the possible exception of structural steel. Shipments of foreign cement arriving in the harbor.

Denver—Hollow tile and sewer pipe stocks low. Lumber trifle below normal. Plenty of brick.

(Continued on p. 622)

Japanese Preparing to Order Quantities of Supplies

Lumber, Steel, Concrete Mixing Machinery and Galvanized Steel Sheet Inquiries Principal Factors

Japan will be in the market for about 260,000,000 ft. of lumber within the next few months, as a preliminary order, the Department of Commerce has been informed. How much of this is to be purchased in the United States depends upon price and delivery. Japan will also seek some steel in this country, but probably not more than 20,000 tons has already been placed with American and Canadian mills.

The U. S. Department of Commerce will take no part in the purchases to be made by Japan, its duty ending with the message asking the co-operation of building materials manufacturers to prevent undue price advances in the face of an emergency. The Japanese Government is assured by the Department that American materials manufacturers will be able to handle all orders from Japan with promptness and dispatch. All transactions will be handled directly with the building materials producers by the Japanese, particularly through such agencies as the Metropolitan Reconstruction Board at Tokio.

Numerous small orders have already been received by American producers for electrical equipment and accessories, wire, wire nails and galvanized steel sheets. Considerable interest is also displayed in motor trucks and railway car equipment. The Ransome Concrete Machinery Co. of Dunellen, N. J., has already shipped an initial order consisting of twenty-seven concrete mixers and several steel towers to the devastated area. Lumber requirements are estimated at three billion feet.

CONDITIONS OF MATERIALS STOCKS IN IMPORTANT CENTERS

Stocks on hand in approximate figures, example: (Common brick, Denver, 5,000,000); time required for delivery of carload lots to city job, example: (Sewer-pipe Atlanta, 4 to 5 days); and stocks on hand in general terms, example: (Cement, Cincinnati, scarcity)

	San Francisco	Los Angeles	Denver	Minneapolis	Detroit	Chicago	Cincinnati	New Orleans	Atlanta	Philadelphia	New York
Sewer pipe.....	Stocks in good shape	No shortage	Supply low	Ample	Normal	Supply low; del. take 1 week to 10 days	Plenty	Scarcity of 4-in. pipe	Del. take 4 to 5 days	Supply ample	Small stocks in sizes above 6-in.
Cement.....	Well supplied	Sufficient; foreign shipments arriving	Enough	Plenty; del. prompt	No local shortage	Enough	Scarcity	Plenty	50 to 60 cars	No stocks in city; null del. prompt	Dealers' stocks small; mill del. prompt.
Lime.....	Fairly well stocked	Plenty	Sufficient	Enough	Well supplied from local and Ohio kilns	Plenty	Enough	No shortage	70 cars	Normal	Markets well supplied
Common brick.....	Large reserves	Demand being met	5,000,000	Large stocks	Plenty in dealers' yards	Sufficient	Ample	Sufficient	Plenty	Supply coming in to meet demand	Heavy reserves being piled in Hudson River district
Hollow tile.....	Plenty	Supply equal to demand	Stocks low	Sufficient	Small supply	Del. take one week	Plenty	Enough	4 to 5 days	Small stocks	Dealers' stocks small; prompt del. by way of
Lumber.....	Heavy shipments to Japan	Demand not greater than supply	Trifle below normal	60,000,000 ft. in Twin City yards	Stocks decreasing at approach of inventory	Del. take 30 to 60 days	Sufficient	Stocks low on yel. pine	Plenty	Well stocked except West Coast lumber	Del. take 4 to 5 weeks from mill
Asphalt.....	Unlimited native reserves	Native reserves	Sufficient	Ample	Moderate stocks; del. prompt.	Plenty	Ample	No market	60 to 70 cars	Great scarcity	Heavy reserves in N. J.
Structural steel.....	Plenty structural; low on rivets	Supplies now up to requirements	Warehouses well stocked	Enough in warehouses	No shortage	Del. on reinforcing bars take 30 days	Pipe stocks low; other steel items plentiful	Normal	4 to 5 cars	Supply ample for small tonnages	Warehouse stocks sufficient; demand light

(Continued from p. 621)

Minneapolis—Stocks of all materials ample with deliveries prompt. Lumber stocks trade below normal with an estimated 60,000,000 ft. in Twin City yards, wholesale and retail.

Detroit—Small stocks of hollow tile on hand. Lumber reserves decreasing at approach of inventory time; dealers buying on hand to mouth basis. No local shortage of cement but scarcity reported in nearby localities owing to heavy demand by State Highway Department.

Chicago—Sewer pipe stocks low; deliveries take from one week to ten days. Lumber mill shipments take

from thirty to sixty days. Japanese demand has not yet affected the lumber market in this district. Hollow tile demand slightly above normal for this time of the year, deliveries take about one week.

Cincinnati—Scarcity of cement; plenty of all other building materials.

New Orleans—Stocks of pine lumber are low but the demand is inactive. Plenty of other building materials available, with the possible exception of 4 in. sewer pipe.

Atlanta—Plenty of brick and lumber. Between fifty and sixty cars of cement, sixty to seventy cars of asphalt, about seventy cars of lime and from four to

five cars of structural steel on sidings.

Philadelphia—Scarcity of asphalt and hollow tile. Well stocked with lumber with the exception of West Coast fir. No dealers' stocks of cement held in reserve as prompt mill deliveries render this practice unnecessary.

New York—Heavy reserves of burned common brick being piled up in Hudson River district. Brick shipments are prompt, and distribution is greater at the present time than during the peak of the building season. Plenty of other construction materials with the exception of sewer pipe. Small stocks in city in sizes above 6 in., mill deliveries slower than month ago.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual biddings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Oct. 4; the next, on Nov. 1.

Steel Products:	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal
Structural shapes, 100 lb.....	\$3.64	\$4.00	\$4.20	\$3.40	\$3.55	\$4.20	\$3.60	\$4.10	\$4.00
Structural rivets, 100 lb.....	4.40	4.75	4.90	3.75	4.25	5.30	5.00	4.75	6.00
Reinforcing bars, 3 in. up, 100 lb.....	3.54	3.50	+3.95	3.20	3.45	3.85	3.65	4.10	3.90
Steel pipe, black, 2½ to 6 in. lap, discount.....	44%	-53%	43%	47%	53-55%	36%	33.2@42.2%	35%	47.42
Cast-iron pipe, 6 in. and over, ton.....	63.60	-55.00	63.00	60.20	60.50	69.00	62.00	62.00	60.00

Common Labor:									
Common labor, union, hour.....	.75	.3550@.55	.55
Common labor, non-union, hour.....30	.30@.50	.82½	.50@.55	.35@.50	.50	.56¼@.62½	.30@.35

Explanation of Prices—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or - signs. For steel pipe, the prevailing discount from list price is given: 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. Labor—Concrete laborers' rate, 93¢; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit, stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu. yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5½ x 8 x 11¢. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 98.83). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.42; 6-in., \$119.

Changes Since Last Week

The present irregularity in demand is reflected in the firmness in prices of certain materials and a tendency toward weakness in certain others. Linseed oil, for instance, which is considered a barometer of the paint trade, has taken an upward turn due to higher flaxseed and increased demand. Raw oil advanced 2c. in San Francisco; 3c. in New York, Minneapolis and Denver; 4c. in

Atlanta and 5c. per gal. in Dallas.

Lumber is also firmer. Pine advanced \$1 in New York and fir 50c. in Seattle and \$3.75 per M. ft. in Denver, during the week. A slight decline, however, is reported in Minneapolis on Douglas fir timbers.

Reinforcing bars advanced 15c. per 100 lb. and sand, 11c. per cu. yd. in Dallas. Hydrated finishing lime rose

\$2.50 per ton and common lump, 10c. per bbl. in Atlanta. Local stocks of steel bars are exhausted in Dallas.

Steel pipe discounts advanced 8 points and c.-i. pipe dropped \$5 per ton in Atlanta. Brick dropped \$1.50 per M. in Dallas and common lump lime, 50c. per ton in Montreal. Bars remain firm at \$2.40 with plates and shapes at \$2.50 per 100 lb., f.o.b. Pittsburgh.

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

E. J. MEHREN, Editor
FRANK C. WIGHT, Managing Editor

Volume 91

NEW YORK, OCTOBER 18, 1923

Number 16

A Cabinet Officer Needs Educating

THE authoritative statement of Dr. Work's position in the Reclamation Service case, as set forth in our Washington correspondence this week, indicates that the Secretary of the Interior does not even now fully appreciate the significance of his action in removing an engineer from the head of an engineering bureau and placing there a so-called business man. He is still obsessed with the notion that engineering is merely the "building of dams and the digging of ditches" and that dam building and ditch digging can be carried on just as well under the superior direction of an unsuccessful banker as it can under a successful engineer. When he has had somewhat more experience with the intricacies of government irrigation—or possibly when he has received some instruction through the medium of a congressional investigation—he will know that reclamation is a continuing engineering problem, that requires for its supervision somewhat more than the acquaintance with human nature that presumably is the principal asset of the politician and business man, and which the Secretary assumes to be a non-existent characteristic in an engineer. At any rate he is already learning that what he thought was merely a quiet little political maneuver has assumed proportions that threaten his whole administration.

Municipal Bond Market Overloaded

RECENT indications are that the market for municipal bonds is overloaded. A few weeks ago Detroit received no bids for a bond offering and more recently a fairly large offering by Dallas, Texas, brought no bids the authorities were willing to accept. For several months past higher interest rates have been necessary to secure bids favorable enough to relieve public authorities of worry over impaired credit standing. All this will have some bearing on the fate of bond issues up for approval at the November elections as well as upon the volume of construction work to be offered next year. By now, most of the items to be voted on in November have been fixed beyond change, but thinking voters will consider the bond market and it will also be taken into account by the public authorities in passing ordinances for later bond elections and in placing on the market bonds already authorized.

Convention Contrasts

THOSE who attend many society conventions in the course of a year marvel at the contrasts thus afforded. Most convention programs are overloaded with papers, a considerable percentage of which are not suited to reading and discussion on a convention floor. Too rarely a convention program is as well planned and carried out as was that of the American Public Health Association at Boston last week. Although—or was it because—the convention met in nine sections,

besides the general meetings, there was plenty of free time for trips of inspection, and these were well organized. There was also time for discussion of the papers and reports, at least in the Sanitary Engineering Section. It was hinted, above, that sectional organization explains the well ordered character of the A. P. H. A. meeting. Doubtless that had much to do with it, but a little earlier the New England Water Works Association had a convention at Burlington which, with no section meetings, was also well ordered and afforded ample time for discussion. What many of our technical societies need is program planning of a kind that will keep the papers and reports so limited in number, and insure that they are of such a character, as to bring out full and free discussion—for as a rule a society paper not of the sort to elicit discussion should not find a place on a convention program.

Activating Superpower

HERBERT HOOVER, with characteristic directness and clarity of purpose, has taken the only initial step that will lead to the development of the so-called superpower scheme for the Eastern industrial zone. The engineering advantages and difficulties of this huge undertaking have been thoroughly analyzed and made public; there remains now the tremendous inertia of public and private action to be overcome. It is true, as the Secretary of Commerce says, that the federal government could step in to initiate the superpower work by direct action, but that is incompatible with either public policy or private needs. But the government is doing a much more useful work in bringing together the power interests and the state authorities in the Northeastern states to work together to develop plans whereby the numerous legal and statutory restrictions to interstate power transmission may be overcome. Once the public agencies can get together with some joint workable plan, the private interests and the state engineers can proceed along engineering lines to develop the technical requirements of joint production and transmission of power. The Department of Commerce can be trusted to continue to activate the study of superpower and in so doing will hasten the day when it becomes an actuality.

Special Privilege at Muscle Shoals

WHETHER or not the political prophets are right in saying that Henry Ford's first public statement on the Muscle Shoals proposition, noted in the news pages, is the opening gun in his presidential campaign is no concern of ours. We are concerned, however, with the unfair position the Detroit manufacturer takes toward the whole Muscle Shoals controversy. To read his statement one could well believe that an adequate and scientific offer for the government property on the Tennessee was being blocked by predatory political and

financial interests. This is not a fact. What Ford neglects to mention is that his offer is in contravention of the established water power law of the country and that the system of payment proposed is in contravention of any accepted law of economics. Mr. Ford is becoming more and more egocentric. It is perhaps natural that he should come to think he is a law unto himself, but he and his advocates must be made to understand that even his demonstrated efficiency in some lines does not place him in a privileged class before the law. If he is in earnest in his wish to make fertilizer and to distribute cheap power from Muscle Shoals (and this is the first time he has actually said that he would make commercial power) he should make a proposition which not only will adequately reimburse the government in accordance with law but will give more assurance of that intention than the mere spoken word of a man—a superman if you will, but one who can hardly transmit his human qualities by word of mouth to the corporation which will succeed him in a few years.

Winter-Work Records Wanted

LACK of data on winter operations is hampering the work of the agents of the Department of Commerce who are investigating seasonal construction. So few contractors in any community have kept close account that it is virtually impossible to formulate definite conclusions as to the percentage of workable weather and temperature effects on efficiency and costs in that community. These data are needed if we are going to arrive at any true findings concerning the remedies for seasonal work—for two reasons particularly: (1) Since winter construction is an economic problem, owners must be shown that it is profitable to build in cold weather, and (2) winter construction is a different problem in different temperature and storm areas. Very complete data of winter construction operations in Atlanta, Ga., if they should happen to exist, would obviously be of limited service to contractors in Cleveland, Ohio. There is apparently in the difficulties of the Department of Commerce agents an opportunity for associations of builders and general contractors to perform a needed service for the industry—the collection of winter construction data, each organization in its own community. All organizations functioning intelligently this winter would leave very few sections of the country unrepresented in the records of the Department of Commerce. There is a duty to be performed by contractors' associations in discovering the conditions of cold weather work and winter idleness.

Labor Difficulties Up to Building Public

THAT those who complain of labor ills in the building field have the remedy in their own hands has been demonstrated in Chicago for the past two years. While everybody in the building business has not supported the Citizens Committee to Enforce the Landis Award, enough did do so to keep down strife and permit a period of building during an unprecedented boom without interruption of any kind except the delays incident to an extraordinary over-demand for labor. In twenty months building permits have exceeded a half billion dollars and the rate now is about two and one-half times that of any previous period. Graft has gone. Union and open-shop men work side by side

without smashing each other's heads. Labor leaders are said to be afraid to call strikes fearing a revolt of the men, although usually a boom period and labor scarcity is considered the heyday of the walking delegate with his arrogant orders to strike on the least provocation. The committee has brought 15,000 to 20,000 men into the city and placed more than 50,000 men through its employment offices.

Naturally, there have been sporadic cases of rioting, bombing and slugging; the committee members have been threatened but the criminal element has been about worn out. Two police have been killed but public sentiment forced the state's attorney to act. Special prosecutors were put to work; \$100,000 made available and the volunteer services of prominent lawyers obtained. Twenty labor criminals are wearing prison stripes and several more are in jail, for which the decent laborer is as pleased as the bystanding public.

Apprentice schools have been started. Bricklaying, plumbing, sheet metal work, painting and carpentry can be learned without the onerous restrictions of the unions.

Recently certain contractors who have out-of-town all-union jobs have pulled away from the Landis Award committee and rumors to the effect that the committee was losing ground and would disband have been circulated. At a recent meeting of the Chicago Association of Commerce and a few days later of the contractors and architects the members of the committee, T. E. Donnelly, James A. Patten and John W. O'Leary, emphatically denied any thought of quitting, but they made it plain that the fight was not that of the contractors, nor of the committee, but of the building public. Active support from the public is essential. If the enthusiastic applause greeting this request is any criterion, the committee will stay on the job, and Chicago building will continue indefinitely unhampered by labor troubles.

How Shall We Gage Water-Supply Purity?

NOTHING could better illustrate what many people—wrongly, we think—deprecate as an insidious, rapid and far reaching usurpation by the federal government of powers rightly belonging to the state, than the strong control of the character of public water supplies which is being gained by the Treasury Department through the United States Public Health Service. Based, as are so many other kinds of federal control, on the interstate commerce clause of the Constitution, the Public Health Service put out some ten years ago a bacterial standard for water supplied for drinking purposes on railways and other interstate carriers. This standard it is now proposing to make more rigid and although it has no power to impress these requirements on municipalities the nature of the situation is such that the new regulations will have a potent effect on all public water supplies.

We question neither the power nor wisdom of the federal government in its interstate control nor the choice of the agency for the purpose, but we do urge caution in the methods employed in exercising the control lest there be a reaction against this and other instances of federal control and more particularly lest the Public Health Service, in attempting to promote the public health in one field—a field in which practice is far in advance of that in most other municipal fields—

cause a retardation of progress along other lines which would bring far greater returns for the same expenditure of money. The danger that we have in mind is one that is incident to all work along highly specialized lines unless there is constantly a broad vision of all the needs in collateral fields, or, in other words, a consideration of relative values.

Whether foreseen or not, the Public Health Service standards for drinking water are rapidly becoming the standards for all public water supplies; that is, they are being so considered more and more by sanitarians, state boards of health, the courts, the press and, gradually, the general public. The press and the general public, in particular, have little knowledge of the fact that the B. Coli standard now in use and proposed to be made still more rigid is merely a tentative index of pollution—much like the albuminoid ammonia, chlorine and total bacterial count standards that preceded it. Although this is thoroughly understood by the specialists, it does seem at times as though even they set up the B. Coli standard as a fetish, though there is as yet no certain way of telling whether the B. Coli found in water are of human or animal origin.

In view of such limiting conditions to the B. Coli index, great care should be taken against raising it unduly, since there is no certainty of getting health results commensurate with the possible heavy expense entailed to comply with the standard. This seems to be all the more important since, as we suggested at the outset, the municipal water supplies of the country as a whole seem to be far in advance of almost any other branch of the municipal service coming under the general head of sanitation and public health. If and where this is the case, should not the Public Health Service, and the state and local health services as well, be concerned first of all with the raising of other sanitary and public health services to the level already attained by the public water supply, rather than with forcing the water supply to a still higher level of quality, measurable merely by an index of pollution beset with much uncertainty?

In raising this question we fully understand that the regulation of the quality of water supplies on interstate railway trains and steamers must of necessity be conducted from the viewpoint of protecting passengers from all parts of this and other countries, rather than from the viewpoint of a given individual city. We also understand fully that the water supply of many cities, and perhaps of nearly all the cities of many states, is already well up to the present Public Health Service standard and perhaps has reached the level of the proposed standard or can be brought there quite readily. At the same time, it is evident, from the utterances of federal, state, and local officials engaged in the various conferences that have thus far been held over the proposed new standard, that a considerable number of water-works officials of the country, including those from a number of important cities, are deeply concerned as to the difficulties and expense involved in meeting the proposed new standard—in fact, have not met the old one—and that there is also considerable concern on the part of all the classes just mentioned as to whether the B. Coli standard alone should govern.

Although there has been considerable talk as to the advisability or possibility of giving large weight to a sanitary survey of each water supply, the present indication seems to be that for some time in the future

at least, as has been the case in the past, many supplies will be judged chiefly from the bacterial standard. This is due in part to the comparative readiness with which bacterial analyses can be made and interpreted as compared with the sanitary survey. It should be noted that the Public Health Service has no facilities for conducting either bacterial analyses or a sanitary survey. It must rely almost wholly upon state and local supervision of water supplies, merely accepting these or else, in cases of material doubt, refusing certification on the strength of reports that come to it from state sanitary officers.

If there be uncertainty, as there certainly seems to be, as to the weight that is to be given in the future to the sanitary survey as compared with the B. Coli index, the uncertainty is still greater as to paying much if any attention to the typhoid and other statistics of a community that may be regarded as reflecting the character of the water supply. From the very narrow viewpoint of water supply alone this is natural enough, but from the broad viewpoint of public health, both of a given community and of the country as a whole, it seems very unfortunate. Inasmuch as the B. Coli index is an index only and an uncertain one at that so far as its real significance is concerned, why not give material weight to the vital statistics of a community, or that part of them known to be affected by the character of the public water supply, in certifying a water supply from a community, say like Providence, R. I., where during the whole year 1922 and so far in 1923 there was not a single death from typhoid fever? There are many other cities which are in the same general class as Providence so far as complying with either the old or the proposed new B. Coli index is concerned. Some of these communities, like Providence itself, are voluntarily taking steps that will lead within a few years to a water supply of a different and probably much improved character. In much the same way the trend in whole states is toward a materially higher standard of water supply than now exists.

What we urge is careful consideration of the possibility of establishing and administering a water standard along broad enough lines to guard against the possibility that a city may be forced to expend a relatively large sum for the compliance with an arbitrary tentative standard of water quality, with no certain evidence that any lives will be saved or sickness prevented thereby, when the required expenditure could be used for other purposes that would undoubtedly save more lives and prevent more sickness in the community in question. Such consideration should not, of course, go so far as to endanger any traveler on railway trains or steamboats who drinks water taken from that city, even though it be but once a year, but after all what is the better index of the safety or danger of a given water supply: a B. Coli content that may be due to causes that have nothing whatever to do with any disease to which human beings are liable or the vital statistics of the community constantly using the water supply?

We think a careful weighing of the elements that may properly enter into a standard for water supply, including the broader health considerations we have mentioned, will show conclusively that much weight should be given to the sanitary survey and to the vital statistics of a community in deciding whether or not its water supply is safe for use on interstate trains and steamers.

Rigolets Bridge Built to Stand Hurricanes: L. & N. R.R.

Each Pier a Concrete Cylinder Sunk 80 to 113 Ft. Below Sea Level on Gulf Coast—Steel Shells Sunk and Concreted—Truss Spans and Draw—Construction Equipment Floating or on Piles

BUILDING A BRIDGE in an exposed situation subject to tropical hurricanes and to heavy wave action is the unusually difficult condition to be met in the reconstruction of the Rigolets Bridge on the main line of the Louisville & Nashville R.R., about thirty miles east of New Orleans. This bridge crosses a tidal pass known as the Great Rigolets, connecting Lake Borgne and Lake Pontchartrain. The general situation is shown in Fig. 1.

Hurricane Conditions—For many miles on each side of this crossing the railroad traverses a salt marsh along the Gulf coast and is subject to violent hurricanes which at times have caused severe damage to the railroad and to the bridge. During storms of 1909 and 1915 several of the plate girder spans were carried

porary trestles in place of these sixteen spans have been maintained since the storm mentioned.

In its present state, therefore, the bridge consists mainly of two groups of steel girder spans on piers of creosoted piles, these groups being separated by a 560-ft. stretch of creosoted pile trestle with open deck. One group has five through girder spans of 59 ft. 8 in., and the other has twenty similar spans of 52 ft. 10 in. and a 236-ft. through-truss swing span. There is a navigable channel on only one side of the pivot pier. The base of rail is about 13 ft. above mean sea level. Creosoted pile trestles form the approaches. It will be noted by the plan, Fig. 1, that all the old steel spans are on the skew, the piers being arranged in line with the direction of the current. These pile piers are described farther on.

In the new bridge, Fig. 2, which is intended to be substantial enough to withstand any hurricane likely to occur on the Gulf coast, there will be eight through-truss riveted spans 330 ft. c. to c. of bearings, with a 414-ft. swing span. This gives a total length of 3,097 ft. c. to c. of end piers. Special provision will be made for anchoring the spans to resist the force of hurricanes. Ten concrete cylinder piers will support the spans, but the cylindrical pivot pier will be filled solid and the west end pier will be of the usual rectangular plan and supported on piles. By approach grades of 0.3 per cent at the west and 0.25 at the east end, the elevation is raised so that the height from mean sea level is 18 ft. to base of rail and 13 ft. 4½ in. to lowest point of steel.

Location and Approaches—In order to avoid interference with traffic during construction, the new bridge is located alongside but somewhat diverging from the present structure, being placed at a sufficient distance to be clear of all wreckage from the latter, which has been damaged several times by storms. The greatest distance between the structures is 200 ft. At the east end is a curve of 1 deg. 40 min.

Long timber trestles will form the approaches, as the marshes over which the line is located are too soft to sustain the roadbed. There will be 7,769 ft. of trestle at the east end and 3,435 ft. at the west end all with 12-ft. spacing of bents. Creosoted piles in six-pile bents are used for that portion of the trestle which will remain permanently, while green piles in four-pile bents are being used for the portion which will be filled for a solid embankment.

The greater part of the trestling will be filled, and owing to the soft ground it is expected that when this filling is completed there will be more material below the marsh level than above it. Since the placing and compacting of the fill will thus extend over considerable time, the trestles will be constructed of ample strength to carry trains for several years, thus allowing ample time for the embankment to settle and also providing for placing additional material as settlement occurs.

Substructure—Special interest centers in the design of the substructure, with piers sunk in loose material, standing in deep water and exposed to heavy storm waves (see Fig. 2). After careful consideration of these violent lateral forces it was decided to adopt piers

FIG. 1—RECONSTRUCTION OF RIGOLETS BRIDGE;
L. & N. R.R.

away by the combined action of wind, waves and current. In violent storms the waves reach a height of about 10 ft. above mean sea level or 2 ft. above the bottom flanges of the present girders. The tidal range is only about 15 in.

Tropical hurricanes originating at the eastern end of the Caribbean Sea and blowing through the Gulf have a diameter of about 250 miles, with a velocity of translation of about 12 m.p.h. and a rotary velocity as high as 125 m.p.h., as determined from observations made south of New Orleans. It is this rotary velocity which does the damage. At the bridge the wind may blow in any direction, depending upon the position of the center of the storm in relation to the structure. In the pass the line of current makes an angle of about 64 deg. with the bridge. The highest current velocity determined by measurements is 4.2 miles an hour, when the water was about 4 ft. above normal level and the center of the storm was between Mobile and Pensacola. But the maximum velocity due to hurricanes has never been determined, since men cannot stay on the bridge during these storms and registering instruments could not be used under such conditions.

Old and New Structures—The present bridge at the Rigolets was reconstructed in 1902, but the storm of 1909 destroyed eight of the deck girder spans. A temporary timber trestle was built to close the gap, and in 1911 seven 60-ft. through girder spans were built in place of the original spans. The hurricane of 1915 destroyed sixteen of the girder spans, and these have never been replaced, since the railway company had intended to build an entirely new bridge when financial conditions permitted. For this reason tem-

FIG. 2.—TRUSS SPANS AND DRAW ON DEEP CYLINDER PIERS

of annular or cylindrical form, the design of which is shown in Fig. 3. In each pier the portion sunk below the bed of the Rigolets will be 34 ft. in outside diameter, while the upper part will be 28 ft. in diameter, the change in dimension being made by a square offset. In both portions the central well will be 16 ft. in diameter, giving a wall thickness of 6 and 9 ft. in the upper and lower portions respectively. This wall will be of reinforced concrete and a 6-ft. slab or cap will form the top of the pier to support the bridge seats.

For each pier a cylindrical steel shell or caisson will be sunk, having dimensions conforming to these above noted. Typical construction of these cylinders is shown in Fig. 4. The sinking will be done by open dredging, but arrangements have been made for capping the shell at any required height with a steel dome, so that the pneumatic process may be adopted if necessary to sink through logs or other obstructions. The annular space between the inner and outer shells will be filled with reinforced concrete as the piers are sunk. When the pier has reached the intended depth the bottom of the well will be filled with concrete to a depth sufficient to insure distribution of the load over the entire base area for the pier. For the pivot pier, however, this filling will be carried to the top of the cylinder and will be formed with a recess 13 ft. square and 18 in. deep to receive the steel grillage supporting the center stand of the swing-span turntable.

In the design of the piers no allowance was made for the steel shell, the reinforced-concrete cylinder being designed to have ample strength and stability in itself. It is expected that the piers will be sunk to depths of 78 to 113 ft. from mean sea level to the cutting edge, or 70 to 80 ft. below the bed, but the actual depths may be varied according to conditions encountered in sinking.

Foundation Conditions—The maximum depth of water below mean sea level at the site of the new bridge is about 45 ft., while under the present bridge it is about 57 ft. It is considered manifest that there has been some scour under the latter and it is the purpose to sink the new piers to such a depth as to be stable in spite of any probable amount of scour.

Borings made on the site of the new bridge do not show great uniformity, the material varying from soft black mud near the bed of the pass to stiff yellow clay, fine sand and some gravel. The mud is of considerable thickness under the shallow water near the shores, but there is very little of it in the deeper water. It is expected that the cylindrical piers will be founded either on stiff gray clay or hard packed sand. The

formation of the bed of the pass and of the adjoining salt marshes has been built up evidently with silt from the Mississippi River at a time when this territory formed a part of the delta of the Mississippi.

Pier Construction—The bottom section of each double-shell steel cylinder, about 27 ft. 10 in. high above the cutting edge, will be built up on a dock and then floated to position, where part of a circular cofferdam of steel sheet piling will have been driven. The remainder of this piling will be driven after the shell is floated into position. The purpose of the cofferdam is to avoid the influence of current and to reduce the effect of scour. The cylinder will be sunk by interior dredging assisted by water jets, the shell being built up and concrete filling placed as the sinking proceeds.

Typical details of the steel shells are shown in Fig. 4. They will be of $\frac{1}{4}$ - and $\frac{1}{2}$ -in. steel plating, with interior angle rings to which twenty-four radial braces are bolted. This bracing will be furnished for two piers only, being removed in advance of concreting and thus salvaged for the next piers. The conical shell for

FIG. 3.—TYPICAL CONCRETE CYLINDER PIER

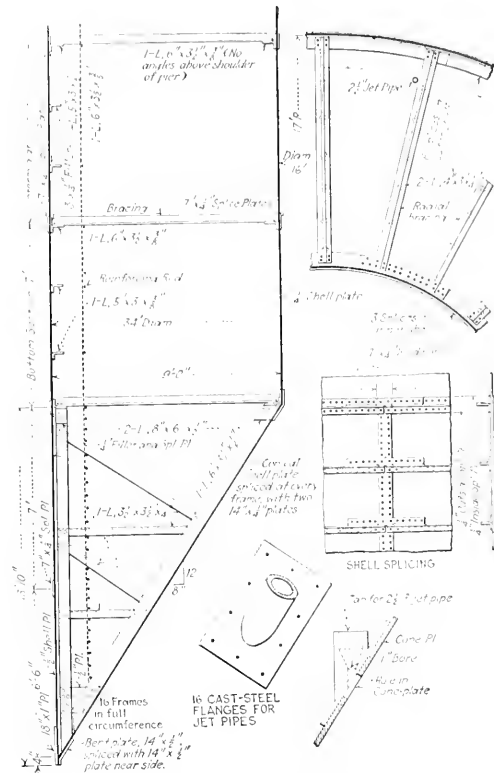

FIG. 4—STEEL SHELL FOR CONCRETE PIER

the cutting edge is braced by sixteen frames and has sixteen cast-steel flanges for 21-in. jet pipes. Each bottom section, 13 ft. 10 in. high, will be set up complete in the shop and all other shell plating will be fitted to templates at the shop to insure accurate fit. All joints will be calked in the field to make the shell thoroughly watertight. This steelwork will have one shop coat of boiled linseed oil and there will be no field painting.

Concrete of 1:2:4 proportions is specified and will be made with gravel. It will be placed by means of buckets handled by derricks, as the specifications require a mix too dry for chuting. In sealing the well of each pier the concrete is to be placed by a tremie to a height of 13 ft. 10 in. above the cutting edge, after which the water will be pumped out and the concrete placed by buckets. The specifications also require that all laitance must be removed, that green and set concrete must be thoroughly bonded and that all concrete must be made as dense and impervious as possible. In all there will be about 26,700 cu.yd. of concrete. Steel reinforcement will consist of plain round bars of medium steel and it is provided that these must be well protected from moisture on the storage dock before use.

Construction Plant—A contract for the piers and foundations has been awarded to the Missouri Valley Bridge & Iron Co., Leavenworth, Kan., on a modified cost-plus-fee basis. Docks, camps and floating equip-

ment have been provided but actual construction has been held up by delay in getting steel delivery.

As there is no solid ground in the vicinity of the bridge it was necessary to build docks for storage of materials and for camp buildings and other temporary structures. Fig. 5 shows the general plant layout. The railway company built a spur track from the main line extending about 300 ft. into water 10 or 12 ft. deep. Docks for the various materials were built adjacent to this spur in water where the depth was sufficient to load barges and operate a tug. Materials are unloaded from cars on the spur onto the storage docks and transferred thence to barges. Docks for the steel and cement house are on one side of the spur and those for the sand and gravel storage piles on the other side. Views of the plant are shown in Fig. 6.

All these docks are on piles 50 to 60 ft. long, driven about 6 ft. c. to c. The steel dock is 40x60 ft.; the covered cement dock, 24x96 ft.; sand dock, 40x50 ft., and the gravel dock 70x50 ft. Camp buildings, tool houses, office, blacksmith shop and other structures are built on piles with the floors about 10 ft. above the ground level; the piles, spaced 8 to 10 ft., are driven about 15 ft. into the soft mud.

For the construction of the bridge piers, twenty barges have been provided, eighteen of which were built new. The power barge, 32x100 ft., is provided with three boilers, two air compressors, a lighting plant, pumps, air receivers and other equipment. This barge is provided mainly with a view to the possible necessity of sinking by the pneumatic process. One of the compressors can furnish air at 100-lb. pressure for operating pneumatic hammers.

The concrete barge, 36x84 ft., is equipped with a sand and gravel bin, concrete mixer, two derricks, two hoisting engines, a boiler for furnishing steam for all engines, a lighting plant, water and fuel tanks. One derrick is placed so as to transfer the sand and gravel from barges to the bin and the other takes the buckets from the mixer and places the concrete in the pier. As already noted the concrete mix is to be too dry for chuting into place.

For excavating material within the steel shell there are two dredge barges 32x72 ft., each equipped with 50-hp. hoisting engines, boilers, a derrick and a light-

FIG. 5—MATERIAL STORAGE DOCKS

FIG. 7—SHEATHED PILE PIERS OF OLD RIGOLETS BRIDGE

ing plant. Two other derrick barges, 26x64 ft., are equipped with 30-hp. hoisting engines, derrick and lighting plant. Other equipment includes a pile driver barge 26x64 ft., with engine and leads; two cement barges 26x64 ft., with houses; three material barges 20x64 ft. for transferring piles, steel and timber; one fuel-oil barge 16x48 ft., two water barges 18x60 ft., two sand barges 24x70 ft., two gravel barges 24x70 ft. and one gravel barge 25x75 ft.

On a pontoon barge 44x44 ft. the steel cylinders will be built to a height of about 14 ft. and then launched. This pontoon is open on top, with sides about 9 ft. high and floor timbers 12x12 in. running in both directions. After the steel shell is built to the required height, plugs will be pulled and the barge permitted to fill with water. One side of the barge, which is hinged, will then be lowered and the steel cylinder launched into the water and towed into position. There are also a steel tug, a gasoline launch and skiffs.

Adjacent to the steel dock a derrick has been erected for transferring the steel from the cars to the dock and from the dock to the pontoon barge and also for building on this barge the bottom 14-ft. sections of the steel cylinders. On the gravel dock is a revolving derrick with a 60-ft. boom, which transfers the sand and gravel from the cars to the docks and from the docks to the barges. Dredging in the pier cylinders will be done by two 1½-yd. clamshell buckets and concrete materials will be handled by three ¾-yd. clamshell buckets. All derricks are provided with bullwheels and swinging engines.

There are a number of pumps, including two with 10-in. suction and 8-in. discharge for operating jets while sinking the cylinders, and also two hydraulic excavators for excavating the material in the cylinders if it is found possible to handle the material in this manner. A high-pressure oil-engine air compressor is provided on the steel dock for operating pneumatic tools used in building the steel cylinders in the pontoon

FIG. 6—CONSTRUCTION PLANT FOR RIGOLETS BRIDGE
Above, material storage dock and spur track. Below, floating concreting plant.

barge. There are also air locks, air receivers, feed-water heaters, riveting hammers, calking hammers pipe threading machines and the necessary blocks, lines and other small equipment. A diving outfit has been provided in case it may be required in overcoming obstacles in sinking.

The railroad company is building the approach trestles, already mentioned. It has begun filling them with clay excavated under water at a point about twelve miles east of the bridge, as the ground is so low and flat that no dry filling material is available within reasonable hauling distance.

Old Pile Piers—Creosoted yellow-pine piles for the pile piers of the present bridge were of extra large size and 70 to 100 ft. in length, driven with a penetration of 30 to 40 ft. or as much as it was practicable to secure without damaging the piles. Typical construction is shown in Fig. 7. Piers under deck-girder spans constructed before 1910 had 16 piles each. In the later work the number of piles per pier was 30 under through girder spans, 22 under deck girder spans and 34 for piers supporting adjacent through and deck spans. All piers were braced by diagonal rods placed by a diver, and those under through girder spans had horizontal plank sheathing down to the water line on both sides and ends. In the majority of cases where spans were carried away by violent storms the piles were broken off near the mud line, the entire pier being washed out or a few piles of the pier left standing.

Engineers—Designs for both the substructure and superstructure of this bridge were prepared by the engineering department of the railroad, under the direction of W. H. Courtenay, chief engineer, Louisville & Nashville R.R.; J. M. Salmon is bridge engineer; and G. R. Smiley, chief engineer of construction, has general supervision of the work. George G. Bryson, resident engineer, with a staff of assistants, gives his whole time to the work. For the contractors the construction will be under the supervision of E. H. Connor, chief engineer, and C. F. Creever, general superintendent of the Missouri Valley Bridge & Iron Co., with D. W. Hedrick as superintendent in direct charge of the work. The estimated total cost of bridge and approaches is \$3,200,000.

Demand a 30-Ft. Channel to the Sea at Wilmington, N. C.

As a result of the great industrial progress made in North Carolina, there has been an increasing demand for better port facilities at Wilmington, N. C. Along with the ambitious plans for the improvement of the port and the public ownership of the water front and its facilities has come a demand for a 30-ft. channel in the Cape Fear River from Wilmington to the sea. That proposal now is being studied by the Board of Engineers for Rivers and Harbors of the Corps of Engineers. At the present time the ruling depth between Wilmington and the ocean is 26 ft. It is estimated that it will cost \$1,500,000 to provide a 30-ft. channel. While it is admitted by the proponents of the deeper channel that only a small percentage of the ships which likely would call at Wilmington would require more than 26 feet of water, it is pointed out that they must have at least a 30-ft. channel to compete successfully with Savannah, Charleston and Norfolk. Savannah and Charleston have 30-ft. channels. The ruling depth at Norfolk is 40 feet.

Surge Tank and Spillway Combined On Pit River Plant No. 1

Heavily Reinforced Cylinder 60 Ft. in Diameter Provides 1,800 Sec.-Ft. Spillway Capacity Between Tunnel and Penstock

THE SURGE chamber on the Pit River No. 1 development of the Pacific Gas & Electric Co. is designed so that it may also function as a spillway to discharge for short periods the full capacity of an 1,800-sec.-ft. pressure tunnel. This was made necessary by the exceedingly flat grade in Fall River whence this plant takes its water supply and in which raising the water surface a few inches at the diversion dam would back up the water for a mile or two upstream and over-

REINFORCING BETWEEN SURGE CHAMBER AND TUNNEL

flow low farm lands bordering the river. Because of peculiar subterranean storage conditions, annual fluctuations of the surface level of Fall River are normally less than 16 in.

The combined surge chamber and spillway is located as a connecting link between a two-mile concrete-lined tunnel and two steel penstock lines. The lower end of the tunnel is a circular section 14 ft. in diameter and the two steel penstocks are 10 ft. 9 in. in diameter at the upper end. These large openings into the surge chamber introduce complex structural problems in its design. The development of Pit River No. 1 project as a whole was described in *Engineering News-Record*, Oct. 5, 1922, p. 570.

The surge chamber is built of reinforced concrete; it has an inside diameter of 60 ft., a depth of 62 ft. and an external collecting chute or trough encircling the cylinder and leading to a concrete wasteway. The crest of the circular spillway is set at an elevation 6.17 ft.

PLAN, ELEVATION AND SECTION OF SURGE CHAMBER

below that of the diversion weir in Fall River, and is provided with a steel frame about 10 ft. higher for such flashing as the operation of the plant may warrant. The encircling trough is of variable width and depth, designed to carry a flow of 1,800 sec.-ft. Baffle or guide walls are provided in the chute at the lower side to prevent excessive splashing and to keep the waves from jumping over the outer walls. This collecting trough delivers into a concrete chute 15 ft. wide by 8 ft. deep which in turn discharges over a precipitous cliff some 300 ft. above the bed of Pit River.

In drawing plans for the surge chamber and spillway consideration was given to the storage and head required to bring from no load to full load within a reasonable time the two 35,000-kva. generators in the plant served. Fall River is about 200 ft. wide and its flat gradient affords sufficient storage to permit of some desired peaking. It was deemed possible to draw from the river more rapidly while peak loads are being carried and to allow the storage to accumulate during the hours of low load. It was thought that a minimum flow through the plant of 900 sec.-ft. might obtain and the finished concrete crest of the

surge chamber was established at an elevation 1 ft. above the computed hydraulic radiant under this condition of flow. After operating the plant for several months it was at times found possible to reduce the flow to considerably below this amount. Consequently flashboards have been added to permit of raising the water level in the surge tank 3 ft. above the original crest, in order not to waste water during low load hours.

In order to confirm opinions relative to the behavior in the collecting and spillway chutes and especially the height and shape of the various walls required, a small model was made of Spanish cedar to a scale of 1 to 60, the inside diameter of the model being 12 in. Various baffle walls or throat sections were made such that they could be readily inserted between the established surge chamber tank and spillway sections. Water was admitted at the bottom of the tank and allowed to flow over the crest at varying depths. There was a decided tendency for the water to crowd over the outer wall at and near the high points in the floor of the connecting trough, even though a split-water vane was provided. This wall was therefore raised about 3 ft. in working out the final design.

SURGE CHAMBER NEARING COMPLETION

Tunnel enters from left and penstock foundations are being placed at right. The chute discharge over the cliff appears in left background.

Baffle walls of various shapes and curves were tried, as was also a section with no baffle walls. The crest of the water surface under each condition was measured from the top of the outer walls at stated intervals and these measurements plotted. The combination which gave the smoothest results was adopted and constructed. While the full 1,800 sec.-ft. has at no time passed over the surge chamber, the results as noted from smaller flows are reported to be very gratifying and in close relation to those observed in the model.

The shell of the surge chamber was designed to resist hydrostatic pressure in tension with a maximum stress in the steel of 12,000 lb. per square inch. The main reinforcement consists of hoops made of square corrugated bars; these hoops were made in two different diameters which were placed alternately so as to stagger the position of the bars with reference to inner and outer faces of the walls. The size of the bars in these hoops increases from 1 in. at the top to 1½ in. at the bottom and the spacing between hoops, vertically, decreases from 8 in. at the top to 4 in. at the bottom. All laps were made not less than 40 diameters and were staggered vertically in the rows. The laps in the inner row were also kept staggered from those of the outer row. Vertical bars, ¾ in. in diameter, were spaced on 2-ft. centers.

The stresses concentrated in the shell of the surge chamber at the tunnel opening total about 1,000,000 lb. and are effective in a direction tangent to the cylindrical reinforcement. A structural steel bridle was designed to transmit the stresses above and below the opening, with an arrangement of reinforcing shown in the accompanying illustration. The vertical members at either side consist of four 5x4x½-in. angles, four 4x4x½-in. angles and four 1½-in. square bars. All of this acts as tension reinforcement for a concrete beam about 7½-ft. deep into the compression side of which are hooked the 1½-in. square bars used as hoop reinforcing. Two sets of six 1x6-in bars tied these members together at the top and bottom. The inward component of stress or pull was provided for by thoroughly tying the whole anchor block in which the bridle is built to the concrete lining in the tunnel. The tunnel lining is reinforced longitudinally for a distance of about 70 ft.

The penstock openings were handled in very much the same manner, except that advantage was taken of the weight in the top penstock anchor to resist the inward

forces. This anchor was increased sufficiently in dimension to carry safely any and all combinations of forces that might act thereon.

The collecting chute was designed as a concrete "L" section with reinforcing tied into the main shell of the surge chamber and supported on wall piers carried down to bedrock. The downhill or front elevation was treated as a series of arches for architectural reasons only. The laying out of the supporting pier was made somewhat difficult due to the fact that the outside circle was not concentric with the surge chamber, the width of the trough being gradually increased from 5½ ft. at the high point to 10½ ft. at the junction with the tangents from the outer walls of the spillway chute.

The main section of the spillway chute is 15 ft. wide and 8 ft. deep and has a grade of 1 in 7. The side walls are 10 in. thick, designed as L-section retaining walls. The floor is 8 in. thick tied into the sides with reinforcing bars. The chute is located off center with respect to the surge chamber in order to fit the ground contour to best advantage. In order to prevent sloughing of the cliff below the chute from endangering the

SURGE CHAMBER SPILLING

Supports for walkway, on which hand railing is not yet placed, will serve as ashboard guides.

concrete structure, the lower 54 ft. of this chute is designed as a self-anchored cantilever resting on a substantial pier placed some 25 ft. back from the edge of the cliff. Although serious sloughing is not expected the lip was flattened to a horizontal grade and was extended some 5 ft. beyond the edge of the cliff in order to keep the drip well down on the bluff.

The steel frame for flashboards was designed with vertical guide beams or posts at 8 ft. 1 in. centers, tied at the bottom with channels and at the top with angle bands or hoops located along the chords of the circle. No diagonal bracing of any kind was used.

The surge chamber structure was constructed by company forces and considerable difficulty was experienced from the fact that the tunnel operations were under contract and incomplete at the time this work was under way. This complicated the work at the portal entrance.

Concrete was of a 1:2:4 mix throughout. Crushed lava rock from the tunnel dump and a good quality of local sand were used. Hydrated lime in the proportion of 10 per cent by volume of cement was incorporated in the mix. Some leakage appeared immediately after the water was turned into the surge chamber but this soon disappeared and since that time the walls and the bottom are reported to be practically watertight.

Cold Storage Warehouse Has Unusual Design

Insulation Requirements Complicate the Design—Railway Track Enters at Third Floor Level—Asphalt and Plaster Wall-Coating Put On With Spray and Cement-Gun

By STEWART T. SMITH

Architectural Engineer with Van R. H. Greene, New York City

A LARGE brick and reinforced-concrete warehouse of notable design is now being erected for the Terminal Refrigerating & Warehousing Co. in Washington, D. C. The building has a ground area of 29,000 sq.ft., and will include space for cold and dry storage and an ice-making plant of considerable size. The insulation requirements for the cold storage space have introduced some unusual features in the design. The building site is east of 4½ St. S.W. and between D St. and Virginia Ave., where the zoning restrictions allow a total height of only 85 ft. from top of curb to top of parapet wall. In order to secure the greatest amount of floor area, the stories are made 10 ft. high, the roof flat, and the parapet wall only 6 in. high. This arrangement allows the building to have eight stories and a basement.

The floor space of the building is divided as follows: 101,000 sq.ft. of dry storage, 50,000 sq. ft. of cold storage, where goods are kept at a temperature of from 32 to 40 deg.; and 25,000 ft. of space for freezers, where goods are kept at a temperature of from 14 to 32 deg. There is also an ice-making plant of a capacity of 150 tons per day, and storage space for 900 tons of ice. Refrigeration is provided by four compound motor-driven ammonia compressors which provide 450 tons of ice and require 2,000 electrical horsepower per day. The ammonia condensers are located on the roof of the building.

Local truck service for the building is from the ground floor on D St. and railway service by a spur

from the Pennsylvania R. R. which runs into the building at the third floor level. The present track has a capacity of six cars, and the structural frame of the building is so arranged that bays in the third and fourth floors south of the present track can be removed to provide space for a second track. Two elevators

FIG. 1—D ST. ELEVATION

9x17 ft. are provided for the dry storage side of the building, and two elevators 9x9 ft. for the cold storage side of the building. The cars of the latter elevators are provided with special rubber flaps around the edges

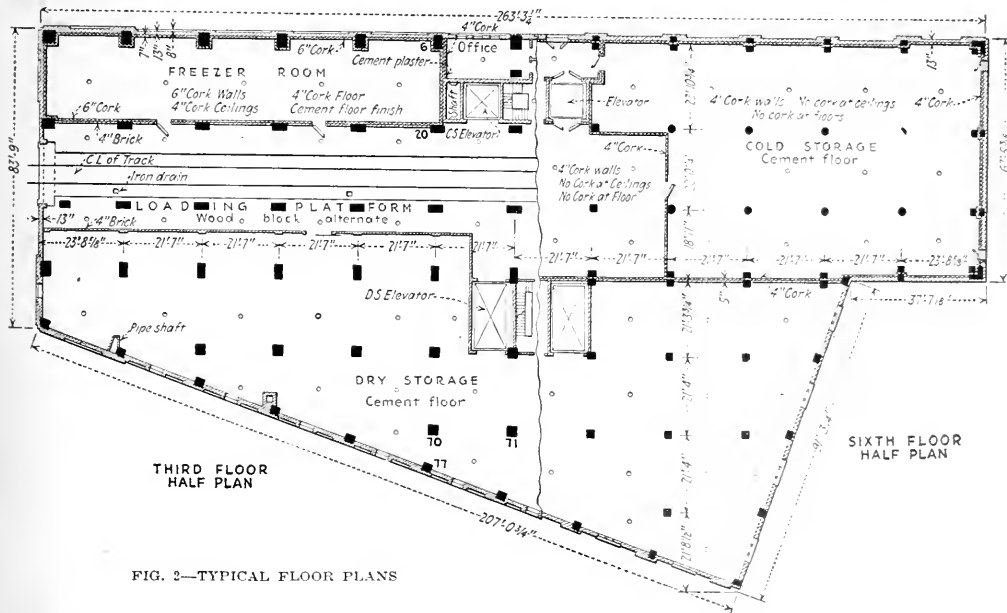

FIG. 2—TYPICAL FLOOR PLANS

FIG. 3—DETAILS OF THE INSULATION

which fit between the car and the hatchway, preventing the escape of refrigeration from the room when the cars are at all landing and the doors of the room open.

Structural Features—The first four floors in the

south half of the building are designed for a live-load of 300 lb. per square foot. All other floors are designed for a live-load of 200 lb. per square foot. This is in addition to the weight of the insulation and wearing surfaces, where insulation occurs on floors.

Beam and girder construction is used for the entire south half of the building and for the second, third, and fourth floors of the north half. The first, fifth, sixth, seventh, and eighth floors and the roof in the north half are all flat-slab construction with drop panels. For all flat-slab design the revised Chicago Code was used with the exception that a stress of 16,000 lb. per square inch for the steel was used to conform with the local code. The location of the columns in the north half of the building was fixed by the dimensions of the freezing tanks in the basement.

The footings rest on a hard formation of clay and gravel and were designed for a soil bearing capacity of 8,000 lb. per square foot.

The columns have a mix of 1:1:2 and rest on pedestals of 1:2:4 mix. A mat of steel is provided in the top of the pedestals to properly transmit the stress over the larger area of the pedestal.

Around the cold storage portion of the building the columns are solid up to a point approximately 7 ft. below the fifth floor. From this point up columns are split to provide for insulation, and wall beams are provided at alternate floors to carry the walls. The anchors which are used to anchor the wall columns to the framework of the building are made of 1½-in. bolts set in pipe sleeves to allow for expansion and contraction.

The supports for the railroad tracks are designed to carry a Pennsylvania engine, total weight of engine and tender 158 tons, and a 126-ton hopper car, plus 50 per cent of live-load for impact. The columns between the present track and the future track, from the second to the fourth floors, were considered as one unit with an unsupported height of 25 ft.

The usual wall girder for flat-slab design was eliminated and no increase in the slab thickness was provided at the wall line. With the elimination of the weight of the wall on the structural frame of the building, it was considered best not to invite additional stress to the edge of the slab by placing a wall girder there.

Retaining walls were designed as slabs from column

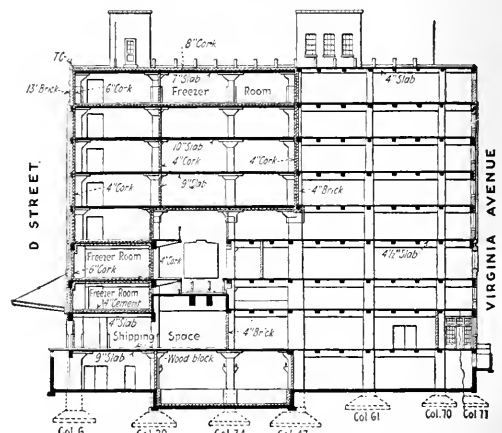

FIG. 4—VERTICAL SECTION OF THE BUILDING

FIG. 5—DETAILS OF THE TRACK GIRDERS

to column with the exception of those along D Street, which were considered as slabs from floor to floor. All retaining walls and the entire basement floor are waterproofed with an integral waterproofing compound.

Insulation Details—All cold storage and freezer rooms are grouped together on the north side of the building and completely insulated with cork. Two layers of pure compressed corkboard in slabs 12 in. wide x 36 in. long and 2 or 3 in. thick, depending on whether the total thickness was to be 4 or 6 in., were used for this purpose. To make this insulation as continuous as possible the walls of the cold rooms were made separate from the structural framework of the building by providing a separate framework to support the walls around the cold storage section. This framework is anchored to that of the building at each floor level. The insulation between the north half and the south half of the building above the fifth floor virtually splits the building into separate units.

Where insulation was applied to the floors, the concrete slab was mopped with asphalt and the first layer of cork was set in this asphalt. This layer of cork then received a heavy mop coating of hot asphalt and the second layer of cork was laid in it while hot, breaking joints with the first layer in both directions. The top surface was mopped with asphalt and a one-ply waterproofing fabric was laid over the entire area, after which a 4-in. concrete wearing surface was applied.

At the roof the same method of construction was used as on the floors, with the exception that the concrete wearing surface was eliminated and the roofing took the place of the fabric.

Where walls were to be insulated, they were first cleaned of all loose particles and then two coats of hot asphalt were shot on with a special gun, filling all the surface pores of the walls and completely damp-proofing them. Two layers of cork were then set up in asphalt the same as on the floor except that the second layer is held in place by the use of wooden skewers. The exposed cork surface is plastered with a cement plaster containing 10 per cent of hydrated lime. The plaster was applied with a cement gun—a departure from the ordinary two-coat hand job for this class of work. The plaster is scored off into 4-ft. squares to prevent unsightly cracking.

Where cork is affixed to a ceiling the first layer was laid in the forms and the concrete poured over it. The second layer was set up in asphalt against the first after the forms had been removed and held in place by wooden

skewers. The exposed cork surface received a plaster finish as on the walls.

Insulated partitions were made by the use of the two layers of corkboard, set together in cement plaster and both exposed cork surfaces plastered. Care was taken to get all rooms completely insulated, and where the corkboard could not be made continuous it was arranged in such a way that heat must travel about 4 ft. through masonry work before entering the cold rooms.

The architectural features of the building were designed by Appleton P. Clark, Jr., architect, of Washington, D. C. The writer had charge of the structural design of the building. All mechanical equipment and refrigerating details were designed by Van R. H. Greene, refrigerating engineer, New York City. The building is being built by the Consolidated Engineering Co., Inc., Baltimore, Md.

Effect of Oil-Well Water on Cements

A study of the effect of various oil-well waters on the setting of cement is being made by the Department of the Interior at the petroleum experiment station of the Bureau of Mines, Bartlesville, Okla. Petroleum engineers of the Bureau of Mines in the course of their investigations are frequently told by operators that the chemical characteristics of waters in their wells will prevent cement from setting. Where surface tests have been made at these wells, it has invariably been found that a good grade of cement properly mixed will set in water from the well. This indicates that conditions in the well such as movements of fluid, agitation by gas, or improper preparation of the hole for cementing are among the causes for the failure of the cement to set. The bureau's engineers are, however, not convinced that cement will set in all oil-field waters and therefore are striving to obtain samples of oil-field waters where difficulty has been experienced in securing a proper set. By collecting numerous samples of waters from various fields in the United States and making tests with cement it is hoped that useful information may be obtained regarding cement failures in wells. The bureau is therefore requesting oil operators to furnish samples of waters from wells where difficulty has been experienced in securing a proper set. Water samples should be sent to the petroleum experiment station, Bureau of Mines, Bartlesville, Okla., accompanied by a data sheet stating owner and well number, location and depth of well, and information regarding the method of obtaining the sample.

Through the Reclamation Country

By F. E. Schmitt

Associate Editor, *Engineering News-Record*

A SERIES OF ARTICLES on Federal Land Reclamation is to start in *Engineering News-Record* next week. It will give a history of the twenty-one years of government irrigation, state the many problems of operation—engineering, agricultural and financial—analyze the various complaints that are being so emphasized by those who are seeking a reform of the current law and methods and seek to present some views as to a constructive policy in the future. Through it all will run the evident theme that irrigation, from planning, through construction to operation, is a continuing engineering problem.

As a part of the preparation of the series Mr. Schmitt is now traveling through the West, visiting irrigation projects, studying developments and interviewing builders, operators and settlers. He will write a series of letters of running comment on the situation as he sees it on the ground. These are not the final result of his trip but they will serve to acquaint our readers with the actualities of reclamation as revealed to an unprejudiced investigator.

This is the third letter. The first appeared in the issue of October 4.—*Editor*.

Hermiston, Ore.

DIFFERENT farmers on reclamation projects take different attitudes when interviewed as to farming conditions and prospects. While generally they complain of low prices for farm products, high prices for all other commodities, and excessive freight rates, some farmers take a more hopeful view than others. On one point all agree: that their condition and the condition of the project would be entirely different, and that they would be doing nicely, if it were not for the effects of the war-time boom and the subsequent forced deflation—the worst in three or four decades. They pay 50 or 100 per cent more than they receive, and they resent it.

Farmers in other parts of the country also are having a hard time of it, and for the same reasons. The reclamation projects are in the same trouble as the farming regions east of the 100th meridian. Yet the condition of the reclamation farmer is blamed on the unbusinesslike and unsympathetic engineer, while the general farmer's condition isn't blamed on anyone in particular.

Unlike the general farmer, the reclamation farmer has ready-made grievances for his troubles, in the shape of the government's water and construction charges, and he can demand of his political representatives that they procure deferment of the charges. These charges are no greater than his taxes, and much less than the interest payment on his mortgage debts; but, though the government charge is theoretically a prior obligation, it can be deferred, while taxes and interest can not. In fact the government claim has pretty well ceased to be a prior lien at all.

Politics in Reclamation—Politics enters into the reclamation business, therefore. It does today and it seems to have done so from the early days on.

The Reclamation Service was not always free to select the most promising projects, and it had some very doubtful projects forced on it.

The reclamation law directed that the attempt should be made to expend in each state the money originating in that state (from sale of public lands), a concession to local jealousies. While the rule was not followed

closely, one of its results is the Umatilla project, surrounding this town, which is not one of the most successful ones; it is hampered by poor soil and at present is only half settled, after a good part of its original area has been withdrawn from the project as not worth irrigating. The Service adopted this project originally because it thought itself obliged to develop a project in Oregon. Umatilla is not strictly a case of political interference, but several other projects are, such as the unfortunate Hondo project, in New Mexico.

Political pressure had the result that on some projects the beginning of repayment by the settler was deferred long after water was supplied; even though the construction charge had been announced and the first payment collected for, the call was withdrawn by the Secretary of the Interior and held up for a number of years, during which time the farmers received the full benefit of irrigation without paying anything but operating charges—a direct loan to them of government money not contemplated in the law. But these and similar special favors to the project settlers were probably less harmful than the demoralization of the relations between the settlers and the Reclamation Service which resulted from constant political agitation of reclamation matters. Public statements by a United States senator that the settlers need not worry about the repayment of the construction charges, and that they might not have to repay them in the end, did not improve the situation.

Several relief bills passed by Congress in recent years further deferred the construction charges. These bills were well-intentioned measures to relieve the hardships produced by deflation. But being blanket measures applying to the worthy and unworthy alike, their effect was neutral or bad rather than good, and they also represent a phase of political in place of business management.

Prominence of Political Influence—The element of political influence forces itself into notice in the present juncture for two reasons. First, it bears directly on the question of operating success of the reclamation projects. A project manager says, "It doesn't seem possible to make a single move without arousing the opposition of one or another interest." Second, the future possibilities of reclamation impregnated with politics appear very menacing with respect to new projects. All sorts of hands are stretched out for money from the revolving reclamation fund. Projects that from an outsider's viewpoint look darkly questionable are being promoted and investigated.

Politics via Washington is perhaps not so serious a matter as local politics, which on a reclamation project almost inevitably centers around reclamation. The men who seek leadership and preferment need issues, and naturally they agitate the farmers' grievances, and the Reclamation Service is the goat. Under private management this particular evil is absent. All that the water users could agitate about is to take over the operation of the system—and this they frequently do not want to do even when it becomes their obligation.

Inflation-Deflation Sequence—Referring to the effect of the price boom and the 1920 deflation, a project farmer said, "Most of the farmers here lost their heads when the war prices came. The wise ones paid their debts and kept the balance of their money; the others bought oil stocks and such like, and some of them even

mortgaged their farms to pay for the stock. Most of them lost their whole investment; and then they were hit by the low prices." Aside from this effect the inflation developed a fantastic rise in land prices and much speculation in land. Farms were sold to adjoining farmers or to outsiders, often on a shoestring. The added burden on the land made the farmers less fit to meet the price conditions later on, when their returns often were less than the cost of production and vast quantities of potatoes were left in the ground or were fed to hogs.

British Sanitary Engineering Practice

Extracts from an address by H. C. H. Shenton, President, Institution of Sanitary Engineers, London, England.

IF IT WERE not for the unceasing work of the engineer, life in our large cities would be impossible. If one follows the course of a drop of water from the time when it is extracted from the river Thames for the London water supply to the time when it again enters the river at Barking or Crossness from the outfall sewer, some idea of the engineers' work may be obtained. It is drawn from a river which receives the drainage of all the Thames Valley above; the sewage of such towns as Oxford and Reading, together with that of innumerable smaller places, houses, factories, etc., enters the Thames above the intake of the Metropolitan Water Board, yet such is the excellence of the work of the sanitary engineer that the water at the intake is practically as good in quality as if it were drawn from the river fifty-five miles higher up. Sir Alexander Houston has shown this. This water is purified by storage, it is filtered, sterilized and pumped, it flows into a system of 6,577 miles of water main, and is eventually delivered for the supply of a house or other building.

English and American House Sanitation—One of the matters most worthy of consideration at the present time is the difference which exists in the practice of English and American engineers. In this country we have for a long time past adopted the principle that all soil pipes shall be kept distinct from bath, sink and lavatory waste pipes. The Americans, on the other hand, appear to use one system of pipes for all purposes. It is obvious that the American system is much more economical than our own, because it saves a double system of pipes, and many branch drains, gullies and manholes otherwise required. If a bath sink or lavatory basin is trapped suitably and if the pipes are ventilated, so that siphonage and air pressure are impossible, it seems that the American engineer sees no objection to the waste pipe being connected direct to the drain or soil pipe. Where this is done there is a saving, first of a separate waste pipe, or system of waste pipes, next of the gully or gullies into which such waste pipes discharge, next of the branch drains running from the gullies to manholes, and lastly of the manholes themselves, in short about half the expense of the work is saved. Seeing that this applies to every new house built and that the present need for economy is great, the matter is at any rate worthy of our consideration.

The Intercepting Trap—Although it is generally admitted that the intercepting trap would be unnecessary in connection with a perfect sewerage system, it does not appear that the average system of sewers in this country is perfect enough to encourage engineers to use the house vent pipes as sewer ventilators. However, cases exist where the interceptor has been omitted wholesale, apparently with satisfactory results, and it seems as if the matter deserved more attention than it has recently received.

Sewer Pipe Joints—In the author's opinion, insufficient attention is given to the probability of expansion and contraction in concrete pipe lines. The extreme rigidity of the ordinary joints is certainly a drawback, seeing that any movement or settlement tends to cause fracture. The Stanton Hume pipe is made with a double socket, into which cement or lead can be calked. The lead joint no

doubt possesses the advantage of slight flexibility. Recently these pipes have been made with ordinary sockets. Some years ago the author used the Brandram joint which consisted of a steel band drawn round the pipe and keyed, while it was covered with hot bitumen. Recently a joint which appears to be somewhat of the same character has been brought forward. The Victualic joint is used for iron and steel pipes. It has been approved by Lloyds for use on ships, and it is also interesting to note that it has been used on a 15-in. cast-iron sewer at Dartford and on a 3-in. steel sewage main at Bradford. The application of this valuable flexible joint to concrete and reinforced-concrete pipes is desirable, but apparently this is still a thing of the future. The cast-iron pipe lined with cement by the centrifugal process is also worthy of note in connection with sewerage work.

Sewage Sludge Utilization—The use of activated sludge as a fertilizer when it is applied to the land is evident. Good results have been obtained; and J. A. Coombs, in the discussion on which followed the reading of his paper before this Institution, said, "the first big town which pumps activated sludge over a sufficient area of distribution will be a pioneer of a practice which will be copied everywhere." The problem of drying this material completely for use as a fertilizer will probably be solved in the near future. There are various possibilities. Dr. Hele Shaw's streamline filter is capable of dewatering activated sludge completely at a very moderate pressure and is certainly a very important factor in the case. Activated sludge has been referred to by Dr. Nasmith as if it were of a highly putrescible character. In the author's experience it does not differ greatly from ordinary humus derived from filters.

J. D. Watson, of Birmingham, A. J. Martin, and others have shown that it is possible to utilize profitably the sludge from ordinary digestion tanks. Some of our large towns, like Bradford, Huddersfield and Morley, extract grease from sludge and sell it; elsewhere, as at Kingston-on-Thames, artificial manure is produced. We have the word of Mr. Watson that utilization of sludge is a duty, and there can be no doubt about it, because Mr. Watson has dealt with the problem on a very large scale at Birmingham, and speaks with knowledge.

French Establish Masons' Apprentice School

Paris Correspondence

A NOVEL movement towards the betterment of masons' apprentices is being carried out in France by the *Chambre Syndicale des Entrepreneurs de Maçonnerie*. A combined home and school has been established in Paris for masons' apprentices where they may perfect their themselves in the diverse specialties of their trade.

It is intended solely for orphans of workers in the building trades who lost their lives in the war and workers who are members of the masons' trade unions.

Pupils are taken from their fourteenth year onward and even if they have already been at work provision is made for those who may be needy to take up such higher branches of their trade as they may be fitted for. Obviously this is an effort to form quickly an added corps of masons in the building trades.

The cost of instruction, food and lodging is at the rate of 7 francs 50 centimes per day, the equivalent of \$1.50 at the normal rate of dollar exchange. After passing technical and practical examinations, the pupil receives a diploma and is granted the grade of "companion," in all save point of age and extended experience a full fledged working mason.

This institution has attracted the attention of the French Under-Secretary for Technical Education and is to be closely associated with the *Ecole Pratique d'Industrie* which is under reorganization.

Pollution of Water Supplies by Coal Mine Drainage

Serious Character of Acid Mine Drainage Shown by Study in a Pennsylvania Bituminous Mining Area—Lime Treatment of Mine Drainage and Other Remedies Considered

BY C. P. COLLINS

Consulting Engineer, Clarksburg Engineering Co., Inc., Clarksburg, W. Va.

POLLUTION of public water supplies by mine drainage has become a serious matter in some parts of the country, particularly in the bituminous districts of Pennsylvania. In 1920, the writer, together with a number of other engineers, was called upon to investigate this problem in Fayette County, Pa., where subsequently the Mountain Water Supply Co., with the Dunbar Water Co. and Pennsylvania R.R. Co. as co-plaintiffs, were pitted against the Sagamore Coal Co. and twenty-eight other coal companies in the most

and thus enters the mine workings. After the room pillars have been drawn, the breaking of the roof and superincumbent strata disturbs the natural reservoirs above, and much more water is, therefore, encountered than in the initial stages of mining. The amount of water which may be expected from a given area of virgin coal, and from the area where pillars have been removed, is wholly dependent upon local conditions and cannot be estimated without a careful study of the flow from mines where like conditions obtain.

The height above the coal to which the disturbance reaches after the pillars are removed is dependent upon the condition and character of the strata above the coal. In some cases the height of the disturbance is very great. To the writer's personal knowledge, pronounced cracks have appeared on the surface where the cover over the seam was 475 ft. This is an unusual case but heights as great as 250 ft. have frequently come under his personal observation. It is evident, therefore, that the drawing of pillars may at times have a far-reaching effect and thus greatly increase the amount of water entering the mine workings.

Quantity of Mine Drainage—To ascertain the quantity of mine drainage that may be expected from a given area of coal, mined under the conditions that obtain in the bituminous coal region, investigations were made in Somerset, Cambria and Westmoreland counties in addition to those made in Fayette County, in Western Pennsylvania. About 30,500 acres of exhausted territory, exclusive of Fayette Co., were covered.

V-notch weirs were placed at various drainage outlets, and careful determinations were made of the area of coal mined out from which the drainage was collected. At all gaging stations, the depth of cover, the character of the overlying strata, and the thickness and quality of the coal were carefully noted. The investigation included all the mines on a given drainage area. After

FIG. 1—RELATION BETWEEN COAL MINE DRAINAGE AND RAINFALL.

important case ever brought in the courts to restrain stream pollution caused by drainage from bituminous coal mines. (No. 1023 in Equity, 1921, Fayette County, Pa.; decided in favor of the coal companies Dec. 26, 1922.) Some of the data gathered by the writer for use in behalf of the water companies will be presented in this article.

In 1904, the plaintiffs built a 251-m.g. storage reservoir on Indian Creek, about $4\frac{1}{2}$ miles above its junction with the Youghiogheny River, in Springfield Township. The reservoir had a drainage area of 109 square miles about 60 per cent of which is underlaid with Lower Measures coal. A 36-in. cast-iron pipe line, with two branches, conveys water from the reservoir to Pittsburgh, one branch via Greensburg and one via Brownsville. Water for railroad purposes is supplied along the pipe line, besides which a large volume of water for municipal purposes is delivered by the Westmoreland Water Co., in the County of Westmoreland. It was alleged that coal mine drainage injured the water for both industrial and commercial purposes. When the dam was constructed the waters from the streams in this area were unsurpassed in purity, with the drainage of only a few mines entering them, whereas at present they receive drainage from about 38 commercial mines. The object of the investigation in which the writer took part was to determine the probable life of the water-supply works if coal mining was to continue without check.

Geological Considerations—During the initial stages of coal mining, considerable water finds its way through the slates and shales immediately above the coal seam

TABLE 1—MONTHLY PUMPAGE OF COAL MINE DRAINAGE AT CENTRAL STATION, NEAR JOHNSTOWN, PA., AND RAINFALL AT JOHNSTOWN

Months (1920)	Pumpage, Million Gallons	Precipitation, Inches

Monthly averages.....	115.5	3.69

* The total precipitation for the year 1920 was 3.07 in. below the yearly normal.

the total flow of mine drainage was determined, the flow of the main stream below the last point of outlet was measured by submerged floats, and under the same weather conditions as obtained during the gaging of the mine drainage. Care was exercised to obtain results indicative of average flows.

FIG. 2—AVERAGE RATE OF MINE DRAINAGE FLOW AND DISCHARGE FROM VARIOUS MINED-OUT AREAS

Mine Drainage Flow in Relation to Rainfall—To study the fluctuations in the flow of mine drainage and the relation of mine drainage flow to rainfall, the records of a large central pumping station near Johnstown, Pa., covering the year 1920, were used. This pumping station received the drainage from 4,282 acres of mine workings, the depth of cover averaging about 250 ft.

Table I shows the monthly pumpage in million gallons per day, and also the precipitation in inches at Johnstown, Pa., for the year 1920, as obtained from E. C. Lorentz, the observer for the U. S. Weather Bureau. The average mine drainage for the year 1920, as shown by the diagram (Fig. 1) was 887 gal. per acre per day, whereas the average precipitation for the same period amounted to 3,310 gal. per acre per day, making the mine drainage 26.8 per cent of the precipitation. This also represents the percentage of percolation through the strata. A study of the diagram clearly shows that the flow of mine drainage is comparatively constant, resembling closely the flow from permanent springs. The minimum mine drainage flow at the station for the year 1920 occurred in November, and was 736 gal. per acre per day, or 83 per cent of the average flow. In other words, we find the minimum flow to be only about 17 per cent less than the average. While precipitation is subject to daily and monthly variation, the mine drainage has only a seasonal variation, excepting where the workings are near the outcrop.

Conditions Governing the Rate of Mine Drainage—Mines operating under a light cover and near the outcrop have a much higher rate of flow than those under deep cover. After the pillars have been drawn, and the strata above the coal are broken, the rate of flow will be greatly increased. In the early stages of development, and even before the pillars have been drawn, we find a higher rate of flow than obtains after the workings are farther advanced.

Fig. 2 shows the average rate of flow in gallons per acre per day, together with the discharge for various areas mined out. The curves have been plotted from actual measurements, only average flows being consid-

ered. The areas mined out in every case were accurately determined, and included both large and small areas. The curve representing the average rate of flow in gallons per acre per day has been plotted from the results obtained in several counties of Western Pennsylvania, covering in the aggregate about 30,500 acres mined out. It is the opinion of the writer that the rate of flow shown by the curve is representative of what may be expected in the bituminous region, where the depth of covering ranges from the outcrop to that of an average of 250 ft. It will be seen that after about 800 acres have been mined out the rate of flow is quite constant.

Quality of Mine Drainage—Sulphur and iron appear in the coal in the form of pyrites, which, coming in contact with air and water, causes chemical changes which produce an acid drainage. The degree of acidity is largely influenced by the amount of sulphur and iron present in the coal seam, and the character of the roof. Under certain conditions, where the strata above the coal are of a basic nature, surcharging the percolating waters with basic constituents, which tend to neutralize the acid in the mine drainage, the drainage may for a time be slightly alkaline, but this condition is unusual. In the examination of the drainage from 160 mines operating in the Lower Measures of coal in Somerset and Cambria Counties in Western Pennsylvania, the writer found only four from which the drainage was slightly alkaline. Table II gives analyses of mine water collected during this investigation which may be considered as typical for mine drainage.

Coal in situ has no effect on the quality of the water in the streams on which it outcrops. It is the impurities, such as iron and sulphur, in the coal coming in contact with air and water after mining is started that produce chemical changes which result in the formation of acid drainage. This condition does not change after the mine is worked out and abandoned, but in general the drainage continues to be acid for

* Sample collected Aug. 10, 1920, at Miller Shaft, near Portage, Cambria County, Pa. Flow about 334,000 gal. per day at the time sample was taken.

† Sample collected Aug. 13, 1920, at Central Pumping Station near Johnstown, Pa. Flow about 3,365,000 gal. per day at the time sample was taken.

Both analyses were made by E. C. Trax, chief chemist, McKeesport Water Co., McKeesport, Pa.

Many other samples were collected in Cambria and Somerset Counties. Those given above represent what might be termed average analyses of mine drainage in the bituminous region.

several years, and comparable in quality to that from active mines. Before mining is started, the coal in place and undisturbed acts as a barrier to the percolating waters above and prevents the water and air from coming in contact with the impurities, and for this reason a virgin field of coal has no detrimental effect upon the purity of the streams.

The beds of streams receiving mine drainage soon become coated with a typical deposit. This deposit protects the rocks of the stream-bed from the action of the acid in the mine drainage, from which it could otherwise obtain neutralizing elements. Therefore, although a stream in its course may become clarified to a certain extent, the acid is largely retained, and the water is not improved in its course, except in so far as the acid content may be reduced by the neutralizing effect of surface waters from tributary streams not contaminated with mine drainage.

Water Supplies for Domestic Use—The presence of mine drainage in a water supply renders it unfit for domestic use. It is impossible to maintain plumbing fixtures on account of the action of the acid. This trouble becomes specially apparent after the water is heated and deposits of ferric oxide are formed on the pipes. This produces a water totally unfit for laundry purposes.

Water Supplies for Industrial Use—Sulphuric acid in the strength encountered in mine drainage attacks iron and steel very readily, as evidenced by the rapid deterioration of pumps and pipe lines receiving such drainage. When water impregnated with sulphuric acid and its products, known as sulphates, is used for boiler purposes, it produces disastrous effects within the boiler, causing pitting rather than extending uniformly over the surface of the metal. The result of pitting is to produce failure much sooner than if the thickness were uniformly decreased. Locomotive boilers are operated under very high temperatures and pressures, thus making the pitting effect much more pronounced than in stationary boilers.

Disposal of Mine Drainage by Dilution—It is probably safe to say that so long as the flow of the stream is 120 times the flow of mine drainage no difficulty will be encountered in allowing the drainage from mines to enter the streams under the ordinary conditions that obtain in the bituminous coal region.

Treatment of Mine Drainage—The treatment of mine drainage so as to render it harmless to streams is in its infancy. The plant of the H. C. Frick Coke Co. at its Calumet mine in Mount Pleasant Township, Westmoreland County, Pa., marks one of the first attempts to treat mine water. (For details of this plant see article by L. D. Tracey, *Coal Age*, July 1, 1920, p. 12.)

Briefly, limestone pulverized to pass through a 200-mesh screen is thoroughly mixed with the mine water by means of a baffled tank and baffled flume, then settled for about four hours in a second tank, then drawn off over weirs and passed to a storage basin. It is estimated that about $\frac{3}{4}$ ton of powdered limestone is used to remove one ton of ferric oxide. If the free sulphuric acid is neutralized, the ferric sulphate is changed to ferric hydrate and calcium sulphate, but the latter is in solution and thus ferric hydrate remains as a byproduct. This material, the settling tank sludge (about 75 per cent water), is reduced to a dry yellow powder by splashing the sludge against a steam heated drum. During the year 1920, the Calumet mine plant produced about six tons of ferric hydrate per day. This material is in demand by companies manufacturing artificial gas for the purpose of removing the hydrogen sulphide present in the gas. It is also one of the chief ingredients of a number of paints.

The Calumet plant is still in the experimental stage but may be characterized as an encouraging step towards an ideal plant.

Suggested Simple Treatment of Mine Drainage—The writer believes that a simple plant could be constructed to treat mine water so that the effluent could be discharged into a stream without seriously injuring the water for water supply purposes. A sketch of such a plant is shown by Fig. 3.

Let us consider that it is required to provide for the treatment of mine drainage from an area of 200 acres of workings. From Fig. 2 is seen that from such an area we may expect an average flow of about 400,000 gal. per day. It has been proved from experiments in the process of sedimentation that very little advantage is gained by retaining the water in the tank for a longer period than two hours. With a flow of 400,000 gal. per day, a tank of the cross-sectional area shown by Fig. 3 and a length of 72 ft. will meet the requirements in this case.

In view of the fact that ordinary limestone contains only about 48 per cent of lime, whereas the calcined stone carries about 76 per cent, it is the opinion of the writer that it would be advisable to use calcium hydroxide (slaked lime) in place of the pulverized limestone, thus avoiding the construction of a pulverizer and mechanical conveyors, and getting more direct contact of the neutralizing element and the mine water. To treat 400,000 gal. per day of ordinary mine drainage would probably not require more than 400 lb. of quick-lime.

The sludge from the settling tank, if it cannot be disposed of on the lines suggested by the experiments at Calumet mine, could be deposited on drying beds, so constructed as to prevent the leachings from contaminating the stream. When dried, the material would be removed to a dry place and covered with earth.

Excluding Mine Drainage from Water Supplies—To the writer's knowledge, no laws have yet been enacted in the states where coal mining is prosecuted to protect water supplies from mine drainage. Moreover, such decisions as have been rendered have been in favor of the coal companies. There remain as alternative protective measures the construction of conduits to intercept mine drainage and the acquisition of mineral rights. Intercepting the mine drainage and discharging it below the reservoir of a given water supply has two very serious drawbacks: (1) If the drainage is carried in pipe lines it would require the use of pipes not affected by acid drainage. Terra cotta pipes would resist the acid but the writer has examined several drainage lines built of this material, and in every case great trouble was encountered by the deposits on the walls of the pipe. While wet, this deposit is very hard and can scarcely be picked off with a knife. When it becomes dry it can easily be reduced to a fine powder by rubbing it between the fingers. To prevent such deposits the mine water would first have to be collected in settling basins. This would make such drainage lines very expensive. (2) The amount of water cut off from use at the reservoir would present a very serious problem in dry weather.

Control of Mineral Rights—The only safe plan in the light of present conditions, and when no relief is offered by law, is for the water companies to gain control

of the minerals on the watersheds where they contemplate the construction of reservoirs for purposes of water supply. This would not only be a great burden to the public on account of the necessary increase in the rates for water service, but it would also be equally as great a blow to the domestic and industrial world by reason of the elimination of large areas of coal from which indispensable fuel must be obtained.

Sealing Abandoned Mines—As has been said, the drainage from abandoned mines is as injurious as that from active mines. The writer tested the drainage

in the United States Bureau of Mines is the proper authority to make an exhaustive study of treating mine drainage so that it may be discharged into streams without dangerous results. This would be a much more efficient method of procedure than to have each state make investigations.

It is very evident that the expense of treating mine water would be no hardship to the operators, as it is an axiomatic principle that the consumer must always bear the burdens incident to coal production. However, if it can be shown that the added expense would

FIG. 3—SKETCH OF SUGGESTED PLANT FOR TREATING MINE DRAINAGE WITH SLAKED LIME

Designed for daily capacity of 400,000 gal. The object is to neutralize acid sufficiently so that, with stream dilution,

it will not injuriously affect water supplies. The flume and tank to be covered with 2-in. plank as frost protection.

from mines that had been abandoned for as long a period as fifteen years and found it to be highly acid.

Under the present regulations of mining coal it would be very difficult to prevent the drainage from abandoned mines from entering the streams, for the reason that the surface is generally broken to the limits of the outcrop of the coal. However, under a strict regulation that no coal shall be disturbed beyond the limits of a 20-ft. cover, and that no openings shall be allowed to be made other than are absolutely necessary for mining purposes, it is the opinion of the writer that abandoned mines could be effectually sealed.

Considering that the coal between the outcrop and the line of about 12-ft. cover is of little value, and cannot be shipped under normal conditions, the loss of coal resulting from confining the mining to a limit of 20-ft. cover would not be large compared with the benefits derived from leaving such a solid barrier to prevent the seepage from abandoned mines from entering the streams.

Suggestions for the Future—There is no hope for relief until legislation is enacted and enforced to regulate the discharge of mine drainage into the streams of such states. However, we cannot expect that any state will pass such an act until an approved and efficient method of treating mine drainage is offered. In the opinion of the writer, the Department of Sanitation

not exceed 10c. per ton of coal produced under normal prices of labor and material (and the writer feels very confident that it would not exceed this) the local water-consuming public would no doubt gladly bear this extra expense, if it could be assured that supplies of pure water could be maintained during the operation of the mines and after they are abandoned. It would be a small price to pay in comparison with the benefits received, benefits so vital to the health and happiness of the people.

To obviate the necessity of treating the mine water from abandoned mines, or at least to have the volume of such drainage reduced to a minimum, it should be unlawful to mine any coal within the area included between the outcrop and the line of 20-ft. cover.

Engineers Should Control Street Traffic

According to C. Augustus Vollmer, of the Los Angeles police, traffic control should be divorced from police duty and given to engineers. Speaking before the Traffic Commission of Los Angeles, he said that traffic control has outgrown its status as part of the duty of a policeman and is now the work of expert engineers, for it has reached the point of a scientific problem involving street capacity and many other similar matters which are out of the scope of a police officer and more in the field of engineers.

Theory and Tests on Duty of Irrigation Water

Discussion of an Article on the "Economical Use of Irrigation Water Based on Tests" in *Engineering News-Record*, by Barry Dibble, B. A. Etcheverry, J. B. Lippincott, Lynn Crandall, A. Lincoln Fellows, and the Authors.

Determination of the actual theoretical, ideal and practical duty of irrigation water has formed the main subject for most meetings of irrigation engineers, operators and users since the Mormons started irrigation in Utah. MESSRS. CLYDE, GARDNER and PROFESSOR ISRAELSEN have made a heroic attempt to bring practice and actual need into consonance by means of a formula developed from carefully observed

tests at widely distributed points. To develop the views on the value of the proposed methods a number of engineers were asked to comment on the article. Below are given the replies of five engineers together with answers by the authors. When understood the method seems to meet with approval, although cautions as to blind use are sounded and accepted by the authors as proper.—EDITOR.

Soil Samples a Better Guide than Formulas

By J. B. LIPPINCOTT
Consulting Engineer, Los Angeles, Calif.

THE AUTHORS have gone into higher mathematics in order to work out the duty of water curves for different crops. Their article impresses me as an unusually complete demonstration of the manner in which the theorist is likely to attack a problem of this kind. I do not consider their mathematical demonstration of any value whatever because there are so many local conditions that enter into this problem of the growing of plants. For instance, adjacent to our coast where we have frequent fogs, we raise crops without any irrigation at all, and these same crops, fifty miles inland, would scarcely germinate. Again, the soil conditions completely modify the amounts of water required for all our crops.

In addition to my engineering work I am interested in three farms. We watch the condition of the leaves on the plants closely and when they begin showing any wilt we know that it is time to serve them with additional water. We also have soil augers and take samples of the soil at different depths from time to time and are guided largely by our observations of the soil samples. I have a superintendent who is a university graduate in citrus culture and these are the methods that he uses. They strike me as being unusually practical and far superior to those proposed in your article.

Farmers' Handicaps Must Not be Discounted

By LYNN CRANDALL
Water Commissioner for Big Lost River, Mackay, Idaho

THIS PAPER is a commendable attempt to find a rational basis for solving the perplexing problem of determining the proper "duty of water" under certain specified conditions.

In applying it to large projects, however, the results of experiments on small plots of ground, judgment and discretion must be used. On the experimental lots the ground is well prepared, adequate help is available, soil moisture conditions are under control so that water can be quickly applied to the entire plot when so needed, and the average experimenter is usually—unconsciously, perhaps—interested in establishing the fact that large yields can be secured with small or moderate amounts of water. The average irrigation farmer, on the other hand, labors under many handicaps. He has to start irrigating his fields before the soil moisture has been fully utilized by the crops as otherwise the crops will suffer before irrigation is completed; he suffers at times from interruptions and fluctuations in the water supply. His available help is often insufficient to see that the water is changed at proper intervals, especially during the night; his ground is often poorly prepared on account of lack of resources, and in many instances he is a tenant with but slight interest in making any permanent improvements. The net result of these various factors is that in practical operation a greater amount of water must be supplied to the farmers than

the amount determined from the irrigation of experimental plots.

If all irrigation projects were settled by ideal farmers, men of practical ability, energy and good judgment, who owned their places free from debt, then indeed might the experimental *y-w* curves be approached in actual practice. The "expectancy curve" of such an event ever happening, however, is one the determination of whose co-ordinates defies mathematical analysis.

Even when allowance has been made for the amount of water to be delivered to the average farmer to irrigate some particular crop, in addition to the amount determined from experimental plots, the first step only has been taken in the solution of the problem of determining the acreage that can be irrigated from some stream of measured runoff. The water requirements for crops like alfalfa are nearly twice as great as those for grain, so that obviously the proportion of the project to be devoted to particular crops will have an important bearing on the water requirements for the project as a whole. It often happens during the early years of settlement of an irrigation project that large areas are devoted to grain. Later the development of the dairy industry, for example, leads to the seeding of considerable areas of pasture, alfalfa, etc., requiring greater quantities of water than the grain which they displaced on the land.

The losses in the canal system from the point of river diversion to the settler's land must be estimated and in the case of large canal systems these losses may consume nearly as much water as the net amount used by the plants. When the requirements at the point of river diversion are thus determined, there still remains the problem of correlating this demand with the records of available river runoff. If a sufficient supply is provided by storage or from the natural flow to supply the demand during the years of average runoff, what will the supply be during the lean or dry years, and how often will they occur? A project cannot achieve a substantial success that furnishes an adequate water supply during three out of five years, with a severe shortage during the other two years.

A large irrigation project with earth canals, where the soil conditions, crops, climate, etc., are such as result in a net duty of water of say 2.25 acre-ft. per acre, for the season, on the land, will generally require not less than 3 acre-ft. per acre delivered at the settler's headgate and from 4.5 to 5 acre-ft. per acre, or perhaps more, at the point of river diversion.

Engineers must share with the promoters the responsibility for many poorly conceived irrigation schemes—largely because of a too ready use of experimental data on "duty of water" without a full appreciation of the necessary allowances that must be made to cover the points mentioned by the writer. In studying the irrigated areas of the western United States, those sections that are prosperous, productive, with good roads and schools, with established land values and permanent and attractive homes, are invariably those which have an ample water supply, generally considerably in excess of the amounts that most irrigation engineers would consider necessary.

Some of the factors that enter into the "duty of water" question can be reduced to a mathematical basis, as has

been done by the authors; the determination of others must rest upon judgment and experience. In general, however, engineers should recognize that the results of experimental "duty of water" tests must be applied to large acreages with caution and with proper allowances, and that the successful productive, irrigated areas are using more water and will continue to use and require more water than the amounts that have been generally considered necessary by most "duty of water" investigators.

Warn Against Waterlogging, Alkali and Leaching

By B. A. ETCHEVERRY

Department of Irrigation, University of California, Berkeley, Calif.

THE METHOD of solving the problem is interesting and is based on the application of economic principles to the results obtained from tests. It is, however, important that the results of these tests be not given undue weight and that the different values obtained for the economic number of acre-inches applied per acre for the different conditions and crops be considered only as illustrative and not the proper values to use in practice. The importance of this is obvious when it is realized that the economic depths derived from these tests are generally considerably in excess of what is required under reasonably good practice and in excess of the quantities which have caused large areas of irrigated lands to be damaged or rendered worthless by waterlogging and accumulation of alkali.

The limited water supply in many parts of our arid states is not sufficient to serve all of the best lands. The economic use of water is therefore of primary importance. It is unfortunate that much of the water used for irrigation is controlled in a large measure by vested rights or sold on the acreage basis independently of the quantity of water used. It is only where water is costly or charged for in accordance with the quantity of water used that there is an incentive for the careful use of water.

Results obtained from tests may be very misleading unless the conditions affecting the use of water are fully considered and the limitations appreciated. Many of the tests have been made on small tracts where the water table is deep down and where the surplus water added to the land passes down beyond the reach of plant roots and is carried away by natural underdrainage without raising the water table. These tests often give larger yields than are generally obtained over a large area of irrigated land. The larger yields and the relatively free subsoil drainage naturally cause a greater use of water than that required in practice.

In a large area of irrigated lands the deep percolation loss or surplus irrigation water gradually causes a rise in the water table. A condition of equilibrium is obtained when the surplus water is balanced by the underground drainage and the increased soil moisture evaporation due to the high water table. Unfortunately in many cases this condition of equilibrium is only reached when the water table is so near the surface that much waterlogging and accumulation of alkali result.

A large part of the water applied on the test tracts may be surplus irrigation water, passing down beyond the reach of plant roots. For instance, the experiments made at Davis, Calif., show that with 36-in. depth of water a yield of more than 9 tons of alfalfa was obtained, while the Utah experiments show a yield of about 4½ tons per acre with 48-in. depth of irrigation water. Evidently the Utah tests show a less efficient use of water with probably considerable deep percolatory loss. The yield of over 9 tons per acre on the Davis tract is much larger than that generally obtained in practice. On large irrigated areas in the San Joaquin Valley the yield of alfalfa is not over 5 tons per acre. This is in part due to the effect on the root system of a high and fluctuating water table, which results from more water being delivered to the areas than the quantity necessary to produce the crops.

The yield water curve for wheat from the Utah experi-

ments shows about 46 bushels of wheat with zero acre-in. of water applied and about 57 bushels with about 36 acre-in. of water applied. Evidently the larger part of the 36 acre-in. applied was lost by deep percolation. With this quantity of water added to a large area of irrigated lands, unless unusual natural underground drainage existed, waterlogging would soon occur.

The economic depth of irrigation water to use for the different crops for the conditions and values assumed by the authors of the paper may be justifiable if it will not produce damages of waterlogging, accumulation of alkali and leaching of fertility from the higher lands. If these damages do result, the cost of these damages or of drainage works to prevent waterlogging should be an additional factor to consider in arriving at the economic depth.

Amount Applied in Single Irrigation a Factor

By BARRY DIBBLE

Project Manager, Minidoka Project, U. S. Reclamation Service, American Falls, Idaho

AN EXCELLENT work has been accomplished at Logan, Utah, in determining the effect that modification in the application of water has upon the production of various crops. From the standpoint of the irrigation engineer this study is important as showing the factors that affect the water supply which it is economical to provide in a given case. In much of the arid West there is more good land than there is water available with which to irrigate it. Nearly all future irrigation projects will require a heavy initial investment to get water onto the land. Promoters are tempted to spread the water thinly over a large acreage to make the cost per acre low. When the farmer's turn comes he wants a liberal supply of water so that he may get the maximum crop per acre and avoid part of the work necessary in distributing water efficiently. Somewhere between the two extremes lies the economic mean which the authors are endeavoring to find.

When it comes to the practical application of experiments and formulas for determining the duty of water, there is a factor not considered in this paper which is of great importance; that is, the amount of water which is applied to the soil in a single irrigation. It is well established that the amount of water which the soil will retain within reach of the plant roots is very limited. If the application exceeds this amount, as is usually the case in current irrigation practice, the excess water percolates beyond the depth of the plant roots and ultimately reaches the ground water plane. The soil depth penetrated by the roots, of course, varies greatly with different plants.

Don Bark, in some of his experiments in Idaho, built a concrete cistern 6 ft. under the ground surface in which he caught the water that passed out of the test bed. S. T. Harding by other methods reached similar results on different soils. Both showed that twenty-four hours after irrigation the upper 6 ft. of soil retained an amount of available water equal to only 4 cu. in. per square inch of ground surface, even though a depth of 12 in. or more had been applied. At the end of twenty-four hours the water, particularly on the coarser soils, was still passing rather rapidly downward. In irrigating a field it is common practice to over-irrigate the part near the headgate in order to get sufficient water to the lower end of the field. It is possible for the farmer with some extra expense, care and labor largely to avoid these losses and thus reduce the quantity of water applied to the soil.

The question of the proper duty of water has frequently been before the courts in the West and its determination has often rested upon the testimony of the "practical farmer." With the development of irrigation and the increase in the acreage of lands that must be irrigated from the available water supply, it is becoming more and more important to adopt operating and farming methods which will result in greater economy in the use of water. Because of the great number of variables there is room for much analytical study such as Professor Israelsen and his assistants are giving this subject.

Decision as to Constants Difficult

By A. LINCOLN FELLOWS

Senior Irrigation Engineer, U. S. Department of Agriculture,
Denver, Colo.

THE ARTICLE is a notable step in the direction of a more definite knowledge regarding the most profitable use of water in irrigation. It is particularly valuable in calling the attention of irrigation engineers and managers to the fact that the most profitable use of water in irrigation may depend upon the application of a smaller, sometimes materially smaller, amount of water than is required for a maximum crop production, a fact that is too often ignored. This fact has been previously commented upon by various writers but this is the first deliberate attempt that I know of to present a method that may be used to insure the greatest profits in irrigated agriculture, and I have already made some use of it in trying to arrive at the proper amounts to be used in estimating the probable duty of water in certain regions.

The greatest difficulty lies in the fact that it is hard to decide upon the values for the constants of the formulas that will be of general or even local application, since the cost figures and also the values of agricultural products vary so greatly from year to year that any conclusions reached must be used with considerable caution. It is believed, also, that the discussion might be simplified to advantage by using profit-water curves based on the governing conditions of cases 1, 2 and 3, eliminating the calculus involved, which, though comparatively simple, nevertheless conveys an unnecessary impression of abstruseness to many practicing engineers.

Furthermore, the use of water studies involving calculations with respect to large areas is complicated by the fact that the water will be applied not to a single variety of crop, as in the authors' illustrations, but to a great variety of lands and crops giving different yields with respect to both quantity and value, and requiring different amounts of water. For these reasons I fear that the application of the formulas will in general be limited to more or less academic discussions of the duty of water rather than to determinations of the amounts to be provided by canal systems or for the irrigation of specific tracts of land. Nevertheless, I am of the opinion that the publication of the article will prove to be beneficial to irrigation. The same method has already been used to determine the proper amount of fertilizer to apply to land.

The comments made herein result from discussions held with a number of irrigation engineers and constitute, therefore, a consensus of opinion rather than my own individual thoughts. I am under especial obligations to Julian Hinds, engineer, U. S. Reclamation Service, for a letter regarding the article, some of which letter is quoted herein.

Authors' Replies to Comments and Criticisms

By WILLARD GARDNER

Associate Physicist, Utah Agricultural College, Logan, Utah

FROM THE nature of Mr. Lippincott's premises it would be difficult to make a reply that would be satisfactory to him. He should note, however, that the determination of the empirical $y-w$ curve is an important feature of the proposed method and that the authors have not overlooked the importance of local conditions. A careful record of measured quantities of water applied in accordance with the observations noted in his last paragraph, together with careful records of crop yields, is just the kind of information we would desire for the establishment of this function. By all means, it should not be overlooked that notwithstanding all apparent demand for water as indicated by the condition of the plant and the condition of the soil, it is frequently impossible to apply even a fractional part of the additional water needed without a very careful method of handling a limited supply.

It might be wisely contended that a precise analytical treatment of approximate and uncertain experimental magnitudes is unscientific. Does it not seem probable, how-

ever, that the experimental methods of modern science are adequate for the determination of such functions as the representative $y-w$ function for a given locality with a fair degree of precision, parameters involving the time and also such parameters as are characteristic of sub-divisions of a given locality entering the function only implicitly through the average value?

On the other hand, an eagerness to abandon hope because of inherent difficulties in the analytical treatment is in many cases perhaps the principal obstacle in the way of the solution of some very practical problems.

The statements of Messrs. Crandall, Dibble and Etchevery indicate that they have given the paper careful consideration and it is reassuring to note that their criticisms are constructive. We are aware of the importance of Mr. Crandall's distinction between the amount of water necessary at the farmer's headgate and the amount to be delivered from the river.

To regard the water and the land as a sort of perpetual annuity from which present and future generations must benefit is no doubt the proper point of view, and, as Mr. Etchevery suggests, an attempt to secure a maximum profit per acre or per acre-inch for any one harvest might under certain conditions be like killing the goose for the golden eggs. To introduce the time explicitly, however, obviously increases the analytical difficulties, and experimental data available at present are wholly inadequate to determine how the time should be introduced in any given case. Even were it possible to do this, the rather subtle question may then arise, just what is the maximum for which we are seeking? Are we looking for a maximum value of the time integral or the profits function? If so, what is our upper time limit? Or are we looking for a maximum value of the "present worth" of the "annuity?" In either case we must decide upon the upper limit of a definite integral. It is to be hoped, however, that methods of irrigation, coupled with methods of tillage and methods of cropping, may be adopted which will insure permanent maximum annual profits.

Concerning the "expectancy curve" mentioned by Mr. Crandall, if by careful experimentation the $y-w$ curve is established for a given locality, from this curve we ascertain the amount of water which we would recommend and the question of primary importance is this: Can a careless farmer use economically amounts of water in excess of this amount? The immediate answer to this question is that if his farm is of the average type for the locality he can do so only by using wasteful methods for the water which he first applies and careful methods for that which he applies subsequently. The careful farmer will use the amount recommended as a matter of choice because he will discover himself that this is the proper amount if he is not disposed to adopt it because of our recommendation. If his farm is of the average type he does not need to worry about a $y-w$ curve of his own, his principal concern being to ascertain the appropriate amount of water he should use for his own benefit. Of course if the water costs him nothing he is concerned only with securing a maximum yield.

It is perhaps unnecessary to discuss these various questions that arise in further detail at this time. If we succeed in stimulating an interest in the subject we shall regard it well worth while and shall of course have no objection to any appropriate modification of the proposed method of attack.

* * *

By O. W. ISRAELSEN

Professor of Irrigation and Drainage, Utah Agricultural College,
Logan, Utah

IT IS gratifying to note the substantially correct interpretation of the purpose of the paper. Mr. Crandall has properly emphasized the need for judgment and discretion in the application of our methods of interpretation. Likewise Professor Etchevery urges the need for caution, not so much in the use of any methods of analysis, as in the assurance that the experimental tests are dependable and applicable to the particular conditions confronting the engineer in a given case. It is noteworthy that Messrs.

Crandall and Etchevery urge caution for precisely opposite reasons: First, that the tests being conducted under ideal conditions indicate a need for amounts of water far below actual necessities and second, that because of the free drainage under many test plats, the experiments frequently show a necessity for amounts of water far in excess of those most economical for large projects with a water table near the soil surface. Since the purpose of our paper is to present a rational basis for the interpretation and application of the results of thoroughly dependable duty-of-water experiments we consider it inadvisable here further to consider the difference presented in the comments of Messrs. Crandall and Etchevery. Suffice it to say that in our opinion a few of the many duty-of-water tests heretofore conducted are dependable if properly interpreted, and that it is yet feasible in many western valleys by further experiments to establish the $y-w$ or duty-of-water curve with sufficient precision to be of real value, despite the admittedly large number of independently variable influencing factors. To one of the variable factors, namely, the water capacity of soil and the amount of water applied in a single irrigation, Mr. Dibble gives particular attention. We agree that this factor is vital in the correct experimental establishment of the $y-w$ curve, and we have treated it in some detail in a different publication. (Israelsen, Orson W. and West, Frank L., 1922—Water-Holding Capacity of Irrigated Soils. Utah Agr. Exp. Sta., Bul. 183, pp. 1-24.)
